We regret to announce the death of Dr. Edward Knowles, of Church Road, Higher Tranmere, Birkenhead, which took place on the 5th inst. Some six months ago Dr. Knowles had a serious breakdown of health, induced chiefly by prolonged insomnia. He had to give up his practice entirely for the time being, but it was hoped that the rest and change which he sought would enable him to regain his usual robust health. Unfortunately, however, these hopes were not realised, and recently his condition had caused great anxiety to his family and friends. Dr. Knowles, who was a native of Denbigh, qualified as M.B., C.M.Aberd. in 1881, becoming M.D. in 1884. He set up in practice at Birkenhead between thirty and forty years ago. He gradually acquired an extensive connection, and became one of the best-known medical men of the town. For many years he was Medical Officer of the Tranmere district under the Board of Guardians, and also Vaccination Officer. Although frequently urged to become a candidate for the Town Council, he would never consent, the demands of his large practice fully occupying his time.

Dr. Knowles, who was about 60 years of age, leaves a widow and a son and daughter to mourn his loss.

DR. R. D. SWEETING, OF LONDON.

We regret to record the death of Dr. Richard Deane Sweeting, Senior Medical Inspector of the Local Government Board, which took place on November 10th, in London, aged 57. The deceased, who was the son of Dr. Richard Sweeting, of Clapham Park, was born at Nassai, Bahamas. He was educated at Malvern and Oriel College, Oxford. He was Buxton Scholar at the London Hospital, and was called to the Bar by Gray's Inn, of which society he was Holt Scholar in Constitutional Law. Dr. Sweeting had a large experience in public health work, and he was examiner in that subject at both Oxford and Cambridge and also for the Royal Colleges. For ten years he was Medical Superintendent of the Western Fever Hospital, and for twenty years Hon. Treasurer of the Epidemiological Society of London, afterwards becoming Fellow of the Royal Society of Medicine and Vice-President of the Epidemiological Section. In 1890 he joined the Medical Department of the Local Government Board, of which he had served as temporary inspector during the Cholera Survey of 1885-6. Dr. Sweeting, who held the qualifications of M.D.Dub. and D.P.H.Camb., was the author of an essay on the sanitation of public institutions, which obtained the Howard medal and prize of the Royal Statistical Society; also of a memorandum on vaccination, and of various reports and contributions to medical journals. He married in 1883 the daughter of Mr. William Rothery, of Harrogate, and leaves two daughters.

REVIEWS OF BOOKS.

AIDS TO PUBLIC HEALTH. (*a*)

We admire Professor Sommerville's ability to boil down so much information on water, sewage, soil, air and disinfectants. With all respect for the author and his achievement, the alternative title of "Potted Public Health" suggests itself to us. If the suggestion may be ventured, the author was only in a contrary mood during the evolution of some half-dozen pages such as when he wanders into graphic formulæ. The time spent in reading the book for the purpose of this review passed very pleasantly and left no trace whatever of the tired feeling one frequently experinces in perusing works on this rather heavy subject. This book will certainly be treasured by candidates for Diplomas of Public Health; it will also be extremely suggestive to examiners wondering what questions to ask, and nineteen out of every twenty general practitioners who buy it will stroke their chins with thoughtful pleasure as they read it.

PRECIS D'ANESTHESIE LOCALE. (*b*)

As is generally known, spinal and local analgesia are far more extensively employed on the Continent than in this country, where the majority of surgeons have been slow to recognise their advantages. One reason for the difference is that the art of selecting and administering an anæsthetic has with us for many years attained a high level in the hands of specialists, whereas abroad it has been much neglected.

(*a*) "Aids to Public Health" (Students' Aid Series). By David Sommerville, B.A., M.D., D.P.H., Assistant Professor of Hygiene and Public Health, King's College, London. Pp. 146. London: Bailliere, Tindall and Cox. 1913. Price 2s. 6d. net.

(*b*) "Précis d'Anesthésie Locale." Par G. Piquand, ancien chef de clinique à l'Hôtel-Dieu de Paris. Préface de M. le Professeur Paul Reclus. Paris: Société d'Editions Scientifiques et Médicales. 1913.

In his opening chapter, M. Piquand undertakes to compare these methods, but his capacity for so doing may be estimated by his statement: "La technique de la rachi-anesthésie et celle de l'anesthésie générale sont plus délicates, mais on les acquiert une fois pour toutes: elles sont les mêmes dans tous les cas et pour toutes les opérations." Throughout the book there is too much evidence of the usual faults of the enthusiast. For instance, the reiterated assurance that the patient "n'éprouvera aucune douleur" can hardly be accepted as regards many of the complicated operations included, even when, as is often advised, an injection of scopolamine and morphine precedes, and "quelques gouttes d'éther" are administered at the climax.

If, however, the author's bias be constantly borne in mind, the work will be found to be one of considerable value. The general *technique* of regional analgesia, and of local analgesia more strictly so-called, is carefully described, and there follow several chapters (forming the bulk of the work) in which minute instructions are given for its application in a long list of operations, ranging from removal of warts and extraction of teeth to prostatectomy and Cæsarean section. There are numerous excellent diagrams.

The book being well printed on thin, smooth paper contains far more than many volumes of inconvenient size and weight. It should be useful to the consulting surgeon, for it is being gradually realised that by combinations of local (or spinal) analgesia with light anæsthesia one may in certain cases attain far better results than by relying upon either method alone; and it is certain that a thorough knowledge of local analgesia is most desirable for isolated practitioners, whether working in remote country districts, on board ship, or in distant regions of the Empire.

PRACTICAL MEDICINE. (*b*)

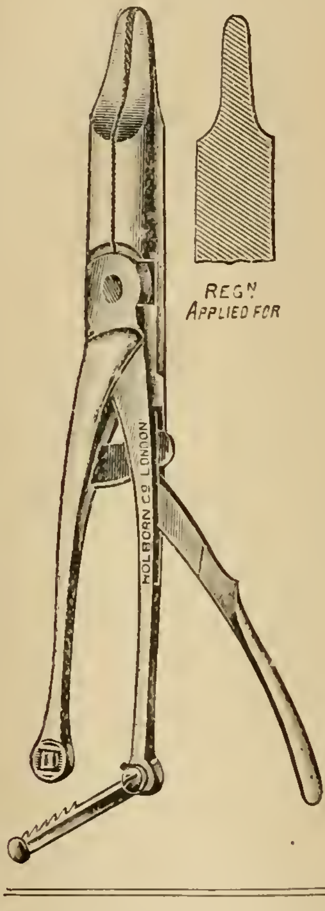
WE have always held that the text-book that best suits the practitioner is unsuitable for the average student, while what satisfies the student as a rule leaves the practitioner's wants unsupplied. The practitioner turns to his text-book to refresh his memory on some point that he has forgotten, or to seek information about some uncommon disease of which perhaps he has just seen a case for the first time. His text-book, to be of use, must supply him with this information and, at least, indicate to him the directions in which he is to look for further light. This being the case, he is apt to judge the book more by what it omits than by what it contains. If he turns to it and it fails to satisfy his want it stands condemned, no matter how much other useful matter it contains. In the student's text-book much may be omitted with advantage, for when what is rare is given with sufficient fulness to satisfy the practitioner, it often merely misleads and confuses the student. The result is the tendency for authors to effect a compromise which is satisfactory to neither party. The book before us illustrates this difficulty of the author. The student preparing for his examinations will be repelled by the mass of material presented to him, while the practitioner will often return from its study with his wants unsatisfied.

PRACTICAL MEDICINE. (*a*)

WHEN a book reaches its fifth edition the work of the reviewer may be said to be at an end; the public has accepted it whether the reviewer likes it or not. When such a book deals with a technical subject and appeals to a public specially educated and qualified to appreciate its subject, there is nothing left for the reviewer to do but to tell the public that a new edition of the book they value has appeared. This duty we hasten to perform, and we feel sure that those who valued the book before will value it more highly in its new dress, and be anxious to recommend it to those who have not previously had the pleasure of reading it. Many will be glad to find that the author has included in this edition the Lumleian Lectures which he delivered before the Royal College of Physicians in 1908. The subject of diseases of the heart is one of absorbing interest, and now when our views on the subject have been again, as it were, cast into the melting pot, the republication of these lectures is most timely. We wish this new edition of Sir James Sawyer's work a similar success to that which the previous editions have well merited.

NEW INVENTIONS.

AN INTESTINAL CRUSHING CLAMP.



"THE crushing lamp here illustrated is one which has been especially made for me by the Holborn Surgical Instrument Company for use during the radical abdomino-perineal operation for cancer of the rectum. The proximal half of the blade is nearly an inch in breadth, in order that the crushed part of the pelvic colon shall be sufficiently wide to permit of easy division between the ligatures. The distal portion of the blade is much narrower, as it is only necessary to crush the meso-colon, for hæmostatic purposes, along the line of division. The advantage of using this clamp is that it greatly minimises the risk of infection when the pelvic colon is divided.

W. ERNEST MILES,
F.R.C.S.Eng."

MEDICAL NEWS IN BRIEF.

The London Lock Hospital.

THE Duke of Devonshire presided at the festival dinner of the London Lock Hospital and Rescue Home, Harrow Road, W., which was held last week at the Whitehall Rooms, Hotel Metropole. Among those present were Lord Kinnaird (Chairman of Committee of Management), Lord Aldenham, Sir Thomas Barlow, Sir Douglas Powell, Mr. J. F. W. Deacon, Sir Malcolm Morris, Sir F. Champneys, Mr. H. S. Littleton, Mr. F. A. Bevan, Sir Clifford Cory, Sir W. Lancaster, Sir A. Pearce Gould, Sir A. Downes, Sir R. Anderson, Sir John Collie, and the Mayor of Paddington.

The Chairman, in proposing the prosperity of the Institution, said it had been called into existence to grapple with a very serious question, and it had been able to do much not only in the way of actually bringing comfort and recovery to the patients, but also in the way of enabling them to start on a new and reformed life. The nature of the evil with which they had to grapple had recently been brought very vividly to public notice, and it was highly satisfactory to gentlemen present that the public conscience had been awakened. A substantial step in advance had been taken in the appointment of the Royal Commission, and any information in the possession of this Institution would be most willingly placed at the disposal of the Commission. The Lock Hospital had to deal not only with a social or a national evil, but an economic evil of far-reaching importance. He asked them to regard any help which was extended to it not only as an act of generosity but as an investment

(*a*) "Diseases of Children. A practical Treatise on Diagnosis and Treatment for the use of Students and Practitioners of Medicine." By Benjamin Knox Rachford. 8vo. Pp. xviii. and 783. With vi. plates and 107 illustrations in the text. New York: D. Appleton and Company. 1912. Price 25s. net.

(*b*) "Contributions to Practical Medicine." By Sir James Sawyer, M.D., F.R.C.P. 5th Edition, with many revisions and additions. 8vo. Pp. 410. Birmingham: Cornish Bros. 1912.

as well, for after all could there be any sounder or better investment than the security for national health?

Lord Kinnaird, in responding, said that he was thankful that the conspiracy of silence in connection with that subject was over, and it was now being realised that there was a side of the question which, under the advice of the clergy and ministers, they might judiciously study and see whether they could not in a few years do something to raise the moral tone in reference to that which led to the necessity for a lock hospital.

Sir Thomas Barlow, in proposing the toast of "The Medical Staff," said that the recent advances in the treatment of the particular disease gave them hope of far more radical and far-reaching improvements than they had ever had before.

Mr. J. Ernest Lane, Senior Surgeon, in reply, said that the male lock hospital was now open, and had accommodation for 40 patients. There was however, some difficulty in obtaining funds for furnishing the wards, but, in view of recent developments and the importance of having them ready at once, he had taken upon himself, with the sanction of the Board, the task of furnishing the new hospital. (Hear, hear.)

The Secretary announced contributions to the dinner fund amounting to £5,430, including the Duke of Devonshire's list of £2,487, and Lord Kinnaird's of 1,078. He pointed out that the total debt of the Institution amounted to £9,155.

Medical Mayors.

The following members of the medical profession have been elected or re-elected to the office of Mayor:—Dr. Preston King (Bath); Dr. Hale Puckle (Bishop's Castle); Alderman Dr. J. Robinson (Cardiff); Dr. S. R. Alexander (Faversham); Dr. R. Jones Evans (Pwllheli); Dr. J. Parkinson Atkinson (Saffron Walden); Dr. J. Rafter (Bootle); Dr. H. Foster-Jeffery (Heywood); Dr. W. L. Davies (Llanidloes); Dr. J. L. Davies (Newport, Mon.); Dr. A. W. Limont (Southport); Dr. Collins (Wenlock).

The London School of Tropical Medicine.

It is reported that Mr. Austen Chamberlain has received from the Secretary of State for India a contribution of £500 towards the fund for the enlargement and endowment of the London School of Tropical Medicine. The fund now amounts to £71,276.

Conference of Non-Panel Medical Societies.

An important conference of non-panel medical associations will be held in London at the end of this month, the exact date of which will be given later. The National Medical Union, with the assistance of several leading London societies, is responsible for convening this meeting. Invitations are being issued to all known non-panel bodies, and the chief object of the conference is the promotion of the federation of non-panel organisations throughout the country. The promoters aim at making the meeting representative of all non-service practitioners, and secretaries of all such associations, and all medical men who are not serving under the National Insurance Act are earnestly requested to communicate with the Secretary of the Union, Mr. J. Webster Watts, 5 John Dalton Street, Manchester.

Congress of the Far Eastern Association of Tropical Medicine

At this congress, which was held at Saigon, an interesting collection of medicaments and medical equipments was shown by Messrs. Burroughs Wellcome and Co. This firm has devoted great resources and unsparing effort to accomplish the production of medicinal agents as nearly climate proof as may be. The exceptional suitability of "Tabloid" products for the East is sufficiently demonstrated by the fact that they have been carried by almost every distinguished African explorer since the days of Stanley and Emin Pasha.

Specially interesting to workers in the field of Tropical medicine was "Tabloid" equipment No. 362 for the treatment of cholera, a compact and thoroughly practical outfit for carrying out the method of transfusion of hypertonic saline solutions with which Major Leonard Rogers has obtained such brilliant results. For the emetine treatment of dysentery, which has leapt into prominence largely as a result of the labours of Vedder in the Philippines, and of Rogers in India, the range of "Tabloid" emetine hydrochloride products is supplemented by the provision of "Vaporole" emetine hydrochloride.

"Wellcome" brand tuberculins, vaccines and sera formed an imposing display of products at the Congress of the highest importance in the treatment of diseases of organismal origin, epidemic or otherwise. In addition to the special cholera outfit, No. 362, a variety of "Tabloid" medicine chests and cases and "Tabloid" first-aid equipments was shown.

A Sanatorium for Merthyr Tydvil.

A sanatorium for the Merthyr Tydvil Union, with beds for 35 consumptive patients, erected at Pontsarn by the Merthyr Board of Guardians at a cost of £8,500, was opened last week by Dr. J. L. Ward, of Merthyr. The site was given by the Earl of Plymouth. The Director of the Welsh National Memorial Association said he believed that the 285 beds in sanatoria under the Association would be increased to 500 by this time next year. The 312 hospital beds were all occupied. Mr. J. T. Hughes, Chairman of the Welsh Insurance Commissioners, also spoke.

The Royal Medical Society, Edinburgh.

The office-bearers of this Society, the oldest of its kind in the Empire, if not in the world, have been appointed for this session as follows:—Presidents, W. A. Alexander, M.B., Ch.B. (senior), J. F. C. Haslam, M.B., Ch.B., Sydney Smith, M.B., Ch.B., and J. H. Boag, M.B., Ch.B., Hon. Secretaries, S. C. Huddlestone and P. A. Bennet Clark; Treasurer, Mr. W. Macrae Taylor, F.R.C.S.E.

Royal Automobile Club as a Territorial Hospital.

At the last meeting of the Committee of the Royal Automobile Club, Dr. H. E. B. Bruce-Potter pointed out that in the event of war calling for the mobilisation of the Territorial Forces in this country adequate hospital accommodation would be necessary in London, and it was absolutely essential that all arrangements should be made beforehand, in order that there might be no delay in converting buildings into temporary hospitals. The following resolutions were thereupon passed:—

(a) That in the opinion of this Committe it is desirable that in the event of war calling for the mobilisation of the Territorial Forces in this country, the Royal Automobile Club be handed over to the London County Territorial Association and other analogous bodies to be a general hospital, and this Committee pledges itself to do everything in its power to secure the carrying into effect of this resolution.

(b) That the R.A.C. be No. 3 General Hospital, as that hospital is commanded by Dr. H. E. B. Bruce-Porter, a member of the Committee of the club, who would therefore be in touch with the R.A.C. staff.

Incorporated Association of Hospitals.

At the twelfth session of the Incorporated Association of Hospital Officers, which has for its object the social intercourse of hospital officials, the study of hospital construction, equipment and management, and other matters affecting the duties and responsibilities of hospital officers, the following subjects are down for discussion at the monthly meetings held at 62 Chandos Street, Covent Garden: "Hospital Appointments and the Election of Duly Qualified Candidates," "Suggestions for Adapting the Existing Voluntary System to meet Present Requirements," "Aids to Promotion for Junior Officers," "The Secretarial Department," "The Steward's Department," "Dispensing and the Insurance Act."

A conference has been arranged for March next between the Association and the Poor Law Officers' Association, and the Saturday afternoon visits include the most recently erected hospitals, concluding in June next with a visit to Birmingham and its hospitals.

NOTICES TO CORRESPONDENTS, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

SHRIMPS FROM SALT.

Among the latest arrivals at the Zoo is a collection of brine shrimps (Artemia), which, it is stated, were "bred from Tidman's Sea Salt." This may look like a case of spontaneous generation; but Mr. J. T. Cunningham, who bred the shrimps, says the explanation is simple and quite scientific. The sea salt is obtained by evaporation, and the minute shrimps' eggs that were in the salt water, though dried, are still fertile when they find their way into the packets with the salt. They will remain fertile for a considerable time, and it is only necessary to make a solution of the salt of a certain strength, and leave it in a warm place until the eggs are hatched and the shrimps are seen swimming about in the water. It should be emphasised that there need be no fear by users of this salt of their finding themselves bathing among shrimps; the time required to hatch them is far longer than anyone would care to spend in the bathroom.

Dr. P. S. (London, N.E.).—Cottonseed oil is a well-known galactagogue. It is only recently, however, that a suitable extract has been prepared for administration to nursing mothers. The active principle is edestine, a protein body, unusually rich in nitrogen. Lactagol (Ext. Gossypii Sem.) is prepared by Messrs. E. T. Pearson and Co., Ltd., 49 Watling Street, E.C., who will readily furnish free samples and literature to any medical man desirous of testing its action.

Meetings of the Societies, Lectures, &c.

Wednesday, November 12th.

Royal Society of Medicine (Section of Surgery: Sub-section of Proctology) (1 Wimpole Street, W.).—5.30 p.m.: Mr. Aslett Baldwin: (1) Notes of a Case of Round-celled Sarcoma of the Rectum with Microscopic and Macroscopic Specimens; (2) Notes of a Case of Recto-uterine Fistula. Mr. Lockhart Mummery: Case of Hæmorrhagic Proctitis. Specimens: (1) Hyperplastic Tuberculosis of the Colon; (2) Cancer of the Sigmoid. Papers: Mr. Sampson Handley: A New Method of Administering Saline after Abdomino-perineal Excision of the Rectum. Mr. Lockhart Mummery: Hæmorrhagic Proctitis, with cases.

Hunterian Society (London Hospital, Mile End Road, E.).—4 p.m.: Clinical Afternoon.

South-West London Medical Society (Bolingbroke Hospital, Wandsworth Common, S.W.).—9 p.m.: Dr. F. Langmead: Chorea.

Thursday, November 13th.

United Service Medical Society (Royal Naval Medical College, Greenwich).—5 p.m.: Surgeon C. Ross, R.N.: Tubercle in the Navy.

Child Study Society, London (Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.).—7.30 p.m.: Dr. M. H. Vaughan: Care of Children under School Age.

North London Medical and Chirurgical Society (Board Room of the Great Northern Central Hospital, Holloway Road, N.).—8.30 p.m.: Clinical Evening.

Friday, November 14th.

Royal Society of Medicine (Clinical Section) (1 Wimpole Street, W.).—8.30 p.m.: Cases by Dr. F. Parkes Weber, Mr. W. J. Midelton, Dr. A. M. Gossage, Dr. A. F. Hertz and Dr. W. Johnson.

Monday, November 17th.

Medical Society of London.—8.30 p.m.: Adjourned discussion on the "Treatment of Neurasthenia." Speakers: Dr. J. Mennell, Dr Claude Fothergill, Mr. Ernest Clarke, Dr. S. A. K. Wilson, Dr. Branson, and others.

Tuesday, November 18th.

Royal Society of Medicine (Section of Therapeutics and Pharmacology).—4.30 p.m.: Paper: Dr. F. Ransom: Diabetic Gangrene and Excretion of Calcium.

Royal Society of Medicine (General Meeting of Fellows).—5 p.m.: Ballot for Candidates for Fellowship.

Royal Society of Medicine (Section of Pathology).—8.30 p.m.: Dr. R. A. Chisolm, Dr. Warren Crowe: The primary Cause of Rheumatoid Arthritis. Dr. E. P. Minett: The Pathogenicity of an Organism Isolated from Non-ulcerating Cancerous Growths (communicated by Dr. J. W. H. Eyre).

Appointments.

Court, A. C. S., M.D., B.S.Edin., Casualty Surgical Officer at University College Hospital.

Dingley, L. A., M.B., B.S., M.R.C.S., L.R.C.P.Lond., House Physician at University College Hospital.

Finlay, D. E., M.B., B.S.Lond., Physician to the Gloucestershire Royal Infirmary.

Hern, John, M.D.Edin., F.R.C.S.Edin., M.R.C.S., in Charge of the Ear, Nose, and Throat Department at Darlington Hospital.

King, G. B., M.R.C.S., L.R.C.P.Lond., House Surgeon at University College Hospital.

Letchworth, T. W., M.B., B.C.Cantab., F.R.C.S.Eng., Ophthalmic Surgeon to Out-patients at the Hampstead and North-West London Hospital.

Moxon, Frank, M.B., B.S.Durh., Honorary Ophthalmic Surgeon to the St. Marylebone General Dispensary.

O'Callaghan, H., M.B., Ch.B., House Surgeon at the Hampstead and North-West London Hospital.

Sanders, W. B., M.B., B.S., Obstetric Assistant at University College Hospital.

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Flint (Flint), Matlock (Derby), Warrenpoint (Down), Whitland (Carmarthen).

Farringdon General Dispensary and Lying-in Charity, 17 Bartlett's Buildings, Holborn Circus, E.C.—Resident Medical Officer. Salary £100 per annum, with rooms, attendance, fire, and lighting. Applications to Charles Nelson, Secretary.

Northampton General Hospital.—Senior Resident Medical Officer. Salary £120 per annum, with apartments, board, washing, and attendance. Applications to C. S. Risbee, Secretary-Superintendent.

Bury Infirmary.—Junior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Honorary Secretary, Infirmary, Bury, Lancs.

City of Manchester Baguley Sanatorium for Treatment of Tuberculosis. Assistant Medical Officer. Salary £200 per annum, with board and residence. Applications to the Chairman of the Hospitals Sub-committee, Public Health Office, Civic Buildings, 1 Mount Street, Manchester.

Births.

Fraser.—On November 3rd, at 2 Cambridge Road, Hastings, the wife of Simon J. C. Fraser. M.D., of a daughter.

Tinne.—On November 7th, at Oak Cottage, Grassendale, Liverpool, the wife of Dr. P. F. Tinne, of a son.

Vernon.—On November 6th, at Wordsworth Lodge, Shirley, Southampton, to Dr. and Mrs. Rupert Vernon—a daughter.

Marriages.

Dick—Wallace.—On November 8th, at Highgate Presbyterian Church, James Reid Dick, M.B., B.C.Cantab., Scarborough, to Davina Orford, daughter of William Wallace, of 5 Broadlands Road, Highgate, N.

Haddow—Shaw.—On November 4th, at All Saints' Church, Woodford Green, London, Archibald Campbell Haddow, M.B., Ch.B., Leeds, to Iris Dorothy, daughter of T. F. Shaw, Esq., Mombassa, and Mrs. Shaw, Bryncyn, Barclay Oval, Woodford Green.

Melrose—Harding.—On November 4th, at St. George's Church, Hanover Square, Surgeon Malcolm M. Melrose, R.N., only son of Chief Inspector of Machinery, James Melrose, C.B., J.P., R.N. (retired), and of Mrs. Melrose, Hayling Island, and Elizabeth Mary (Elsie), eldest daughter of the late Mr. W. Allen Harding, of West Hampstead, and of Mrs. Harding, Moreton Road, Croydon.

Neild—Pruen.—On November 5th, at the Cathedral, Hong Kong, Frederic M. Neild, M.B., of Shanghai, elder son of Dr. Neild, of Tunbridge Wells, to Susan Elizabeth Pruen, second daughter of Dr. and Mrs. Pruen, of Hastings.

Sayers—Hawthorn.—On November 3rd, at St. Michael's Church, Croydon, Surgeon E. B. P. Sayers, R.N., to Dorothy Mayo, youngest daughter of Alfred Mayo Hawthorn, of "Kaliar," South Croydon.

Symns—Sowter.—On November 6th, at All Saints', Notting Hill, James Llewellyn Montfort Symns, B.A., M.B., B.C.Cantab., youngest son of the late Rev. J. E. Symns, M.A., to Claire Hickling Dart Sowter, eldest daughter of John Sowter, of Derby, Civil Servant, retired.

Deaths.

Brighouse.—On November 7th, suddenly, at 93 Tollington Park, London, N., John Brighouse, formerly of Huddersfield, Surgeon, aged 80.

Byramjee.—On November 3rd, at his residence, 3 Rivercourt Road, Ravenscourt Park, Surgeon-Major R. Byramjee, M.D., retired list H.M. Bombay Army, aged 81.

Clendinnen.—On November 6th, at 17 Park Lane, Frederick J. Clendinnen, M.D., of Melbourne, Australia

May.—On November 4th, at 440 Seven Sisters Road, Finsbury Park, Lewis James May, Surgeon, elder son of the late Rev. James L. May, formerly rector of West Putford, North Devon.

Sweeting.—On November 10th, at 7 Fernshaw Mansions, S.W., Richard Deane Sweeting, M.D., Barrister-at-Law, Senior Medical Inspector of H.M. Local Government Board, Whitehall.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, NOVEMBER 19, 1913. NO. 21.

NOTES AND COMMENTS.

The Life of the Panel Doctor. OF all callings, that of the busy medical man in any sphere of practice is one of the most laborious. Among the consultant classes there is the routine hospital work and the necessity of keeping abreast of scientific progress, as well as the actual earning of bread and cheese by ministering to the needs of patients. The work of the panel doctor, on the other hand, is of a kind that leaves little leisure for reflection or study, and is apt to degenerate into a prolonged endeavour to overtake the incessant calls of routine work. If he be a popular man resident in a town he has a crowded surgery to attend to twice a day, with a full list of patients to visit, not to mention an intermittent hail of emergency and night calls. What with the large amount of clerical work required under the Insurance Act, the time available for rest and recreation is whittled away to vanishing point. Well may he wonder why, in order to attain to such a position, he has undergone a long and laborious special education, involving the expenditure of no little energy and self-denial, with an incidental expenditure, probably, of a thousand pounds or more of hard cash. But the outside world that exacts payment from him to the last farthing is wont to appreciate his services on a sentimental rather than on a cash basis: witness the recent outcry against the avarice of a profession that considered forty-eight pence per caput per annum an inadequate sum for medical attendance. Were the gratuitous work lumped into the bargain, at any rate in pre-insurance days, the rate would probably work out at the merest fraction of a farthing per head.

Sir W. Morant on a Day's Panel Work. IF only Members of Parliament could realise the actual conditions of medical practice under the Insurance Act it is probable that future legislation would be of a more generous and sympathetic character. Meanwhile, they might do worse than make a careful study of Sir William's experience of a day's panel work in a Cumberland rural district. A special account of his trip was recently published in the *Pall Mall Gazette*. In the morning of a day chosen at random, he started off with the doctor in his motor-car for hours over hill and dale. Late at night a message came from a distant patient, and Sir William had the novel experience of a motor-boat voyage up Lake Ullswater in a driving storm. This was a fine dramatic finish for the object lesson thus furnished to the head of the Insurance Commissioners. Such an experience can hardly fail to impress upon his mind a lasting visual picture of some of the difficulties of medical work in country practice. It is to be hoped he will not overlook the fact that panel practice in town is not carried on amid romantic environment such as that he found at the foot of Helvellyn. Will Sir William try a day's panel practice, say, in the East End of London, with its morning and evening surgery, its visits in alleys and slums and sordid streets, and, haply, its night with two or three calls to accident and midwifery cases. When one sits down and thinks the matter out it seems incredible that rational men of high skill and education should spend their lives in unceasing and unremunerative toil of this kind. Of all callings that of medicine is most in need of collective protection—call it trades unionism, or any other name you will—some organisation that will enable it to fix its own prices by means of collective bargaining.

The Sandwich Institute. THE appearance of Lord Sandwich amongst the unqualified practitioners of medicine leads one to ask what has become of the Select Committee upon proprietary medicines and kindred matters. Nothing could have been more explicit than the statements of the nobleman in question. His operations were world-wide, and included the treatment of no less than sixty wounded officers in his own country residence. His claims were backed with all the reflected glory of the inauguration of a medico-psychical clinic in a meeting held at University College. It is surely the most unkindest cut of all that this fresh rival of orthodox medicine should be born within the classic walls of University College, London. It is true that a lady doctor, in a speech delivered at the occasion under notice, disclaimed any idea of rivalry with qualified medical practice. The Sandwich way, she explained, was simply complementary and supplementary to it. Her main thesis was that the boon of psychotherapy had hitherto been available only for the rich, but now it was hoped to extend its blessings to the poor. This foreword probably means that a new Institute will be launched ere long for the exploiting of Sandwich methods. Apparently there is no professional body whose duty it is to inquire into and control irregular medical practice of the kind, just as there is no law that deals with it adequately.

Scarlet Fever Convalescence. RECENTLY a police court charge was brought against the medical superintendent and a sister of a fever hospital in the North of England. It was alleged that a boy, aged two years and eight months, an inmate of the hospital, died as the result of a relapse of scarlet fever, due to neglect. It was stated that the boy, because he splashed about, was ordered to the bath-room, where his only choice was between the cold water of the bath and the cold concrete of the floor. The magistrate dismissed the case on the ground that there was not sufficient evidence to send it to trial, and the charge against the superintendant was withdrawn. Without entering into the details of this particular case, it may be desirable to make a few general observations on the treatment of patients convalescing from scarlet fever. First and foremost there is hardly any acute malady that demands more care, especially as regards exposure to cold, than the malady in question. Many a time has it occurred to the writer that the ordinary cross-ventilated ward, with its open windows and ventilators close to the beds, is not scientifically fitted to meet the requirements of the scarlet fever patient. As to cold baths, cold floors, cold passages, thin clothing, insufficient bedding, exposure to draughts, and so on, they are veritable death-traps during convalescence. Comparative mortality statistics of the disease among the rich and among the poor should prove a good deal. Could not the Metropolitan Asylums Board, with its unlimited resources, conduct some investigations with wards specially fitted to protect scarlet fever convalescents from injurious external influences? In view of the heavy scarlet fever mortality tables, such a departure might prove of incalculable value to preventive medicine.

The "Hardy Annuals" at the R.C.S.Eng.

THE "hardy annual" reform resolutions will be brought forward tomorrow at the English College of Surgeons in Lincoln's Inn Fields. They are of the usual drastic nature, and the fact that they appear year after year bears testimony to the spirit of hopefulness and perseverance that are the hall-mark of the true reformer. The following resolution will be moved by Dr. J. Brindley-James: "That this twenty-ninth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College, which as now constituted only represents those Members who also hold the Fellowship; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation." This motion will also be supported by Sir Victor Horsley, F.R.C.S.Eng., Dr. J. Oldfield, Dr. F. W. Collingwood, and others. It is stated that there are over 17,000 Members, but less than 2,000 Fellows of the College, the former contributing over £10,000 a year to the College funds, while the latter contribute less than £3,500. It will be interesting to see whether the old-time controversy, which has raged for over a quarter of a century, will meet with anything like a settlement this year. It may be assumed, however, that in the absence of the President of the College any drastic change in its constitution of the nature contemplated is hardly likely to be perpetrated at the meeting on Thursday.

LEADING ARTICLES.

THE SCARLET FEVER EPIDEMIC IN LONDON.

AT the present moment London is suffering from a heavy outbreak of scarlet fever. The official returns show that at the end of last week there were no less than 3,699 scarlet fever and 1,141 diphtheria patients in the eleven hospitals under the control of the Metropolitan Asylums Board, as against 2,354 and 869 in the corresponding period of last year. These figures illustrate in a striking fashion the Herculean task and the huge responsibility devolving on the body which undertakes the duty of dealing with the infectious disease of London. It is almost appalling to think of what must have happened in the days before there was any public safeguard in existence such as that provided by the Board with its manifold weapons of notification, ambulance transport, isolation, skilled medical supervision and nursing, disinfection, and so on. To some extent the risks and dangers of the earlier days are being reproduced at the present moment. It is announced that, owing to a shortage of nurses, it is impossible to accommodate all the scarlet fever cases in the special fever hospitals of the metropolis. This fact is of serious import in face of the present epidemic. It should render the public more than ever alive to the necessity of early recognition of the disease and of the value of antiseptics in the disinfection of clothing and other articles of environment that have been exposed to one of the most subtle and rapid of all infections that attack the human body. The present, indeed, is a peculiarly apt moment for the issuing of skilled advice to the public as to the most trustworthy antiseptics available for this purpose and the method of application as regards the individual patient on the one hand and his environment on the other. From a scientific point of view, it is much to be regretted that as yet no sound curative remedy has yet been discovered. In all probability, however, the near future will disclose some form of serum or vaccine therapy which will have a prophylactic as well as a curative value. This aspect of the disease might well be made an object of thorough investigation by the scientific staff of the Metropolitan Asylums Board. Of all communicable diseases scarlet fever is one of the most formidable, partly on account of its brief period of incubation and its extreme infectivity, and partly on account of its direct and indirect mortality rates. It is not a little curious that in so common a disease the precise conditions of infection are not fully established. There is, we believe, for instance, at the present time no general scientific agreement as to whether the virus is spread by the desquamations of a patient in the "peeling" stage. It is to be hoped that practical sanitarians will find means of coping effectively with scarlet fever, as they have done in the case of cholera and small-pox.

WHAT OF WISBECH?

THE host of difficulties that have beset the introduction of the National Insurance Act is hardly surprising, when the novelty and the far-reaching scope of that new species of social legislation is taken into consideration. At the outset Mr. Lloyd George ran full tilt into the ranks of the medical profession. For the time being he has left them more or less discomfited, but it is hardly likely that any large section of educated Englishmen will allow themselves to be exploited permanently by any Government. Under wise guidance there may even now be some sort of prospect that matters will settle down and the relations between the State and the medical profession be reduced to a reasonably harmonious basis. A desirable outcome of the kind, however, presupposes a wise and just administration of the Act. Should the Chancellor of the Exchequer and his colleagues adopt a harsh and arbitrary attitude they may not improbably find themselves ere long embarked on a bitter and protracted struggle, from which it is hardly likely that the State, even if it emerged the victor, would add materially to its credit or renown. There are various directions in which it is desirable that prompt official action should be taken. First there is the crucial question as to whether the certificates of herbalists, Christian scientists, faith-healers, and other unqualified practitioners should be accepted for insurance purposes. As the State is responsible for the institution of duly qualified medical practice, it seems incredible that it would thus indirectly sanction gross forms of unqualified practice. Then comes the tragedy of Wisbech. The fight with the medical profession was waged there bitterly. Later came the unhappy death of the imported panel doctor at the moment when he should have been on his defence in a trial for libel against a local medical man. Instead of attempting to allay the storm somewhat by approving a local practitioner in place of the one who died, the local Committee have imported another man—and have thereby declined to hold out the olive branch. Then there is the position of Dr. Meacock, the gentleman who was prosecuting the deceased panel doctor. As the matter did not come to trial he has had no opportunity of defending himself against the scurrilous charges to which he has been subjected. The Isle of Ely Insurance Committee, in which these events took place, declined to request the Insurance Commissioners to conduct an inquiry into the whole affair. The British Medical Association, to its credit be it said, has petitioned the Home Office asking for a special enquiry. So far no answer has been vouchsafed. Surely, no fair-minded Government Department could refuse a request of that kind, to which we take this opportunity of formally and emphatically drawing the attention of Mr. Lloyd George and his colleagues.

CURRENT TOPICS.

Glassworkers and Cataract.

During the last six years some experiments have been made by Sir William Crookes with a view of providing protective glasses to prevent damage to the eyesight of glassworkers and others exposed to severe glare. These were detailed last week at a meeting of the Royal Society. It was explained that the problem was to find a means of cutting off the heat rays that are known to be very injurious to the eyes of glass workers, in some cases predisposing to, if not actually causing, cataract. The experiments had been conducted by mixing various metallic oxides with soda glass. The metals employed for the purpose had been cerium, chromium, cobalt, copper, iron, lead, manganese, neodymium, nickel, praseodymium, and uranium. Each specimen of glass found was cut and polished in plates two millimetres thick. The glass was tested by the spectroscope to determine which of the light rays were cut off, and by a specially devised instrument to find out what proportion of heat rays was arrested. Sir William Crookes announced that he had succeeded in preparing a glass that cut off the chemical, the ultra-violet, and the heat rays, but he could not avoid some light rays being also cut off. It was not an advantage to have absolutely colourless glass, because a very bright light, such as that got from white cliffs, expanses of snow, and electric light, was known to be injurious to the eye, and therefore a tinted glass combining good obstruction to heat radiation and to ultra-violet rays was the best to aim for. He had been able to produce glasses which cut off over 90 per cent. of heat radiation, which were opaque to the invisible ultra-violet rays, and were sufficiently free from colour to be capable of use as spectacles. Several glasses of the type described were demonstrated to the Society, showing how a neutral tint could be produced by making use of both cobalt and nickel. In the course of the discussion that followed attention was drawn to the influence of the presence of potassium in glass in modifying the colours caused by the admixture of nickel oxide, and in replying Sir William Crookes said that while the foreman of a works to which some of the glasses had been sent had appreciated them the workmen refused absolutely to wear them. A great boon will have been conferred upon an important body of operatives if a grave eye affection, such as cataract, can be obviated by such simple means as the wearing of appropriate glasses.

Examinations and Examiners.

In Sir William Osler's introductory address at St. George's Hospital Medical School on examinations and their appendages—examiners and examinees, he mentions a number of obvious facts, which, as usual, are habitually ignored by those who could make practical recognition of them if they only chose to do so. As things are at present examinations are an end and not a means. The student has no time to learn anything about a subject till he has passed his examination in it, and this passing depends almost as much on grasping the personality of the examiner as on a knowledge of the subject. Written papers, on which so many desirable marks depend, can be squared in many ways well known to the expert examinationist. Of course, such skill requires at least as high a quality of intelligence as is needed to obtain a pass mark by simple study, and this is to a certain extent a safeguard, as the examination often gives the student a sufficient interest in the subject to tempt him to dip further into it. For all that our present system of testing knowledge rather than ability is not sound, but it is hard to see any practical way that would not lay itself open to even greater abuse.

General Paralysis in the Light of Modern Research.

Few observations in neurology are of such practical importance as the recent demonstration by Noguchi of the presence of the Spirochæta pallida in the brain in cases of general paralysis. Hitherto, the Wassermann test had been found positive by competent observers in nearly one hundred per cent. of general paralytics. This affection, formerly classed as "parasyphilitic," and often referred to as "parasyphilis," Dr. F. W. Mott, in a recent address delivered at Birmingham at the inaugural meeting of the Midland Medical Society, suggests should be superseded by the term *parenchymatous syphilis.* The use of the ultramicroscope and the Indian ink method of Burri, or the silver method of Fontana, have now made it possible to observe the parasite in the cerebral tissues, even though it may be necessary to go through the labour of examining all the convolutions of the cortex systematically, as Marie, Levaditi, and others, declare. As Dr. Mott remarked, the search for spirochætes in the brain resembles the proverbial hunt for a needle in a haystack, and failure to find them by no means disproves their existence. Possibly the transformation of the spiral form of the parasite into another stage, such as the granule or spore, as observed by Noguchi and McDonagh, may have put observers off the scent for a time. At any rate, it appears that the most recent researches suggest that the active development of spirochætes may lead to the production of toxins which gradually cause degeneration of the neurones. Timely treatment by salvarsan until the Wassermann reaction is rendered negative must now be regarded as the best method of dealing with this fatal form of parenchymatous syphilis.

A New Theory Regarding Diarrhœa.

The *Boston Medical and Surgical Journal* describes a physician's method of treating diarrhœa. He uses common or garden vegetables. "Spinach, turnip greens and mustard tops" are the drugs he pins his faith to. The doses are hardly heroic. "A tablespoonful or more" four times a day for one or two weeks suffices, with a little dry toast, "unless the patients become very anxious for more food." We surmise that most of them do. How far the treatment is responsible for results we have no means of knowing. It seems probable that the author raises an incident to the dignity of a cause. Most of us use green vegetables to the prescribed bounds occasionally and find that such use or omission has no very decisive effect on the internal economy. We wonder where the author cultivates his assumptions. If cabbage were confined to the colorrhœic infant we might suggest a theory of homochromy. It would be a pleasant working hypothesis and as far as we know an original one. "Sweets to the sweet," hydrarg. ox. flav. for the golden staphylococcus and scarlet red for the lurid ulcer suggest themselves. Corrosive tablets, which are frequently coloured with methylene blue, we know are fatal to the bacillus pyocyaneus. We could go on like this for a long time and would evolve a method that would present features no more ridiculous than any other form of *post hoc* therapeusis. As it is we merely suggest, and present the germ of an idea to any enterprising "specialist" who cares to make use of it.

The Ammoniacal Diaper.

One of the small points which make for comfort in an infant is the cleanliness or otherwise of its diapers. The occurrence of an ammoniacal odour thereupon is seldom, if ever, reported to the medical attendant, being thought too trivial for his notice. Attention has been recently called to the subject by Dr. Thomas S. Southworth, of New York, (*a*) who has examined a number of infants whose diapers presented this odour. The urine of healthy infants does not contain ammonia in sufficient quantities to attract notice, for, as a rule, nearly all the ammonia is excreted as urea, but if there exist in the body an excess of unoxidised acids for whose neutralisation the supply of fixed alkalies does not suffice, the ammonia may take the place of these latter and form ammonia salts of the acids which are excreted in the urine. An increased production of acids occurs as a result of faulty metabolism, chiefly when too much fat is given in the dietary. It is found that the administration of alkalies, such as potassium citrate, and a reduction of the amount of fat in the milk or mixture will be sufficient to prevent the ammoniacal odour appearing in the urine. It is not a question of decomposition of the urine at all, but rather one of metabolism, for the ammonia is excreted in a recognisable form, making its presence discernible by the sense of smell. This clinical sign, if present, is of considerable importance, therefore, as serving to indicate the degree to which the infant is digesting its food. The approximate change in the composition of the food will cause the disappearance of the ammoniacal odour.

Nocturnal Enuresis.

That enuresis is a common bane of the night nursery will be admitted by all who have much to do with the care of young children. It is generally considered that inability to retain the urine is a symptom, the cause of which must be carefully ascertained before it can be adequately treated. The subject was recently brought before the Section for the Study of Disease in Children of the Royal Society of Medicine by Dr. W. M. Robson, who thought that more attention should be given to the cases in which hypothyroidism exists, such children being generally undersized and backward, suffering from dead fingers and toes, highly arched palates, and who feel the cold a great deal, especially at night. In these cases the exhibition of thyroid extract in small doses will often act well, promising results having been obtained by Dr. Leonard Williams with half a grain of the dried thyroid twice a day. Dr. Robson believes that, excluding gross disease, such as tubercle or vesical calculus and spinal disease, enuresis is primarily a functional nervous disorder. This being so the condition must be treated vigorously, and any source of reflex irritation, such as threadworms, enlarged tonsils and adenoids, removed. The general health of the child must be carefully built up on sound lines, and the nervous instability controlled by suitable drugs. Atropine treatment, which possesses many inconveniences, is still the one to which the majority of medical practitioners lean. Whether autosuggestion will be more utilised in the future remains to be seen, for several cases benefited by this means have been reported from France.

Cardiff Admits Scotch and Irish to its Hospital Appointments.

There has been a hot dispute at Cardiff over the proposed alteration of the present Infirmary rule leaving open staff appointments to holders of membership and licentiate qualifications. A determined attempt has been made to restrict the posts to men holding the fellowship of the Royal College of Surgeons of England or the membership of the London Royal College of Physicians. Cardiff has taken a broad and progressive view of the matter, and has declined to play into the hands of privileged corporations. The question is no new one: it has been threshed out by the Irish graduates for the past twenty years and more.

(*a*) *Archives of Pediatrics*, October, 1913.

Why should the holders of Scotch and Irish qualifications be debarred from the holding of hospital appointments? Why, for that matter, should members of the English Surgeons or licentiates of the London Physicians be ousted from a similar position? The higher qualifications, as a rule, are gained by young men on mere book-learning, before their capabilities for practical scientific work could by any possibility be ascertained. Viewed judicially, the whole thing resolves itself into a cynical, cold-blooded device for retaining power in the hands of two ancient colleges. Cardiff may be congratulated on having refused to listen to the wiles of these mediæval sirens. Why should it echo the ancient warning that "no Scotch or Irish need apply"? One of the heaviest blows so far bestowed upon this absurd privilege was given a year or more ago in a northern University town. One of its chief hospital posts was advertised for competition, with the appended condition that the holding of the local University degree was an essential condition. Were all the University towns to follow this sensible example, and were Scotland, Ireland and Wales to taboo the English Colleges, it is likely that ere long this worm-eaten privilege would die out. The Colleges, of course, whatever their original attitude in the matter, have no power to alter the conditions of the appointments in question: reform in that direction must come from the governors of the voluntary medical charities.

The Institutional Treatment of Tuberculosis.

The Local Government Board has recently issued a circular letter to the councils of counties and county boroughs of England supplementary to the circular of May 13th with reference to the maintenance grant towards the cost of sanatorium schemes for the treatment of tuberculosis and giving details of the manner in which they propose, commencing with the financial year 1914-15, to distribute this grant. On the submission by the councils of estimates where expenditure is wholly in respect of the scheme of treatment approved by the board and is *prima facie* reasonable, grants will be made during the first half of the financial year up to one-half of the estimated expenditure of the council during the half-year, and in the second half-year grants up to 30 per cent. of the estimated expenditure of the council for that half-year will be paid after allowing for any excess or saving on the preceding half-year. The balance of the grant will be paid after the council's accounts for the whole financial year have been certified by the district auditor. The maintenance grant is available in respect of the institutional treatment of all cases of tuberculosis, including cases of destitute persons who would otherwise be treated by the guardians, and the Board say it is therefore desirable that in the course of time the scheme for the institutional treatment of tuberculosis established by the county and county borough councils should be developed so as to make provision for all classes of the community, including Poor-Law cases. Particulars are given of the details required to be furnished to the Board respecting any proposed tuberculosis dispensary it is desired to establish. Hospital beds are also required for the treatment, and observation of special cases as distinguished from sanatorium beds. The Board add that the concentration in the hands of one authority of the institutional treatment of tuberculosis in any area should lead to increased efficiency and should ultimately result in some economy.

PERSONAL.

H.M. the King has granted to the following officers authority to accept and wear decorations, as stated, conferred upon them by the Khedive of Egypt, authorised by the Sultan of Turkey:—Fourth Class, Imperial Ottoman Order of the Osmanieh.—Major J. Powell, M.B., R.A.M.C. Fourth Class, Imperial Ottoman Order of the Medjidieh.—Captain R. J. C. Thompson, R.A.M.C.

Dr. E. L'Estrange Ledwich has been appointed Consulting Physician to Mercer's Hospital, Dublin.

Sir John Tweedy, F.R.C.S., has been appointed a Civilian Member of the Naval Medical Consultative Board.

We are glad to learn that Sir Donald MacAlister is reported to be out of danger, and it is hoped that he will now make a rapid recovery.

Dr. F. C. Purser, F.R.C.P.I., has been appointed Visiting Physician to Mercer's Hospital, Dublin, in place of Dr. E. L'Estrange Ledwich, resigned.

Professor Ernest Henry Starling, F.R.S., M.D., has been awarded a Royal Medal by the Royal Society for his contributions to the advancement of physiology.

Dr. Robert Hughes, of Stoke-on-Trent, has been elected Chairman of the newly-constituted School Medical Service group of the Society of Medical Officers of Health.

Mr. John C. Bridge, F.R.C.S.Ed., D.P.H.Cantab., Medical Officer of Health for the County of Brecon, has been appointed by the Home Secretary to be a Medical Inspector of Factories.

Sir William S. Church. Bart., M.D., has been elected a Trustee of the Hunterian Museum of the Royal College of Surgeons of England in place of the late Sir Jonathan Hutchinson.

Dr. Valentine Stone, of Montrose, was presented the other day with his portrait in oils, painted by Mr. Fiddes Watts, A.R.S.A., as a token of his services to the community and of the respect and esteem in which he is held in the district.

At the first meeting of the season of the Royal Geographical Society last week, the Society's special Antarctic medal was presented to Surgeon L. Atkinson, R.N., and Surgeon Levick, the surviving medical members of the British Antarctic Expedition, 1910-13.

Dr. Thomas Evans, Medical Officer of Health and School Medical Officer, Swansea, will open a discussion on "Open-Air Education and Sanitation" at the provincial sessional meeting of the Royal Sanitary Institute, to be held at Swansea on November 21st, at 6.30 p.m.

Dr. H. Bayon, Research Bacteriologist to the Government of the Union of South Africa, will deliver a lantern lecture at the Royal Society of Medicine, Wimpole Street, W., on Thursday, November 20th, at 5 p.m., on "The Leprosy Problem in the British Empire, illustrating the Clinical and Bacteriological Aspects of the Disease."

With a view of perpetuating the memory of the late Dr Trevelyan, it has been proposed to place in the General Infirmary, Leeds, a tablet and portrait in bronze relief. The chief part of the cost of the memorial has already been subscribed by his colleagues on the Board and Medical Staff of the Infirmary.

CLINICAL LECTURE
ON
SOME COMMON DISORDERS OF NUTRITION IN INFANCY. (*a*)

By ERIC PRITCHARD, M.A., M.D., M.R.C.P.Lond.,

Physician to the Queen's Hospital for Children, Physician to Out-Patients, City of London Hospital for Diseases of the Chest, Victoria Park; Hon. Physician for Infant Consultation, St. Marylebone General Dispensary, etc.

Before I refer in detail to one or two of the common diseases of nutrition which have been dignified by names, I would like to draw your attention to a few points in the physiology of nutrition itself.

When we speak of the state of nutrition of an animal or of a human being, I imagine that few of us conjure up a very clear picture of the exact meaning of the term we employ. We are apt, for instance, to regard the popular expression "to be well nourished" as synonymous with "being in a condition of good nutrition." As a matter of fact, "to be well nourished," in its more usual acceptation, is to be fat and sleek —to be in the sort of condition in which prize cattle and babies are when they are sent to shows, a very different thing from being in a sound condition of health. I should find myself in a very difficult position if I were asked to define shortly what I myself understand by the term good nutrition. It certainly has very little to do with reserve stores of fat or glycogen. and it certainly has a great deal to do with the functional efficiency or "fitness" of the individual.

When an organism as a whole is said to be in a condition of good functional efficiency or good nutrition, such a statement implies that the individual organs or elements that make up the sum total of its anatomy are also in a condition of functional efficiency. We ought therefore to judge the condition of nutrition by the standard of its functional efficiency rather than by that of outward appearances. There is truth in the statements that a good horse is never a bad colour, and that no one can judge of the time-keeping qualities of a watch by merely inspecting the mechanism, and for the same reason there is truth in the statement that there are few people who can judge of the physiological efficiency of the human organism by a simple examination of its exterior characteristics. There are, however, a large number of physiological functions which betray their merits or defects by visible and objective manifestations. For instance, if the liver does not play its part efficiently in the destruction or combustion of the products of intestinal putrefaction, the individual will be unduly pigmented, or muddy of complexion, or, again, if the kidneys are diseased or incompetent the tissues may be œdematous or the complexion bloated. It requires, however, a very shrewd observer to judge at all accurately of the condition of nutrition of any particular individual by an examination of externals. He must judge by performance and not by appearances.

In order that any organ or tissue may be in a condition of good nutrition, or good functional efficiency, certain conditions are essential. In the first place for good nutrition the organs or tissues themselves must possess normal qualities, qualities which will enable them to perform the duties required of them. Secondly, they must be provided with the food or nutritive material which are required for its metabolic processes. And thirdly, they must be in connection with a normally constituted nervous arc.

The soundness and integrity of this nervous arc is of paramount importance for the nutrition of the highly complex organs of which our bodies are composed.

Let me take, for instance, such an example as the biceps muscle. For this muscle to be in a condition of functional efficiency it must constantly exercise its function or it will assuredly atrophy. The functions of this muscle are not only exercised when it becomes mechanically shortened and it performs external work, but its activities are in constant operation in the mere maintenance of "tone." Tone, however, ceases to exist the moment the integrity of the reflex arc is damaged or destroyed. A never failing stream of sensory or centripetal impulses constantly impinges on the nerve cell which controls the administrative functions of the reflex arc. These centripetal impulses are interpreted by the nerve cell and transmitted to the muscle in the form of an endless succession of trophic or tone-giving stimuli. The moment these centripetal impulses are cut off, as by severance of sensory nerves, or the moment the functions of the nerve cell are dislocated, that moment does the muscle cell lose its tone, or, in other words, fail in nutrition.

Whether, therefore, we take the case of a single muscle, or of the body as an aggregate of many organs, we can see, in the light of these fundamental conceptions that nutrition depends on a large number of factors, chief and foremost among which is the integrity or efficiency of the nervous arc.

Now bearing these facts in mind I would ask you to turn your attention for a moment to a consideration of the first of the factors which I have already enumerated as requisite for nutrition: namely, the food or nutritive supply. In order that nutrition may be maintained, certain food requirements must be observed. The food must contain all the elements required by the various organs for the performance of their functions, and in adequate amounts. If the supply falls short or is excessive in amount, the organism suffers. But, owing to the vast reserve powers of the body, there must be a large excess or a serious shortage to produce any material damage.

I think there can be little doubt that the infant who is breast fed often suffers from a deficiency of iron. At the best of times, human milk is most inadequately supplied with this base, and if, as often happens, the mother is anæmic from loss of blood or from constitutional

---

(*a*) Lecture given to Post-graduates at the Queen's Hospital for Children, April 28th, 1913.

causes, the milk may be conspicuously impoverished in this respect. Under such conditions the infant exhibits a number of symptoms of malnutrition associated with its anæmic condition. One of the most striking examples of malnutrition due to deficiency of one of the essential elements in the infant's dietary is that which is due to the condition known as scurvy. It has long been known that infants fed exclusively on dead or stale foods are apt to develop certain hæmorrhagic symptoms, but the actual cause of the characteristic manifestations of the disease has only recently been discovered. It is now known to be due to deprivation of certain chemical substances called *vitamines*, which exist in most fresh vegetables or animal juices, but are highly perishable when exposed to high temperatures, or if kept for any length of time. The exact chemical constitution of these bodies has not been made out, but they are known to be somewhat complex derivatives of nucleic acid. They have been found in and can be separated from most vegetable juices. Another instance of malnutrition due to the deprivation of an essential element is the condition of osteoporosis, which develops when the organism is deprived of its due requirements of calcium salts. This condition, though bearing certain outward similarities to rachitis, is of an entirely different pathogenesis. I could mention many other pathological conditions which are due to default in the supply, but they are of comparative rarity as contrasted with the pathological conditions due to excess. The organism has many defences against excess, whether with respect to one, many, or all of the elements in a dietary. The organism can defend itself against indiscretion of this kind by vomiting, diarrhœa, storage, combustion, or excretion, but each of these prophylactic measures entails some pathological penalty which can be recognised as a special symptom of malnutrition.

In my opinion the commonest cause of malnutrition in infants is decomposition of excess of food in the bowel, against the consequences of which diarrhœa and vomiting are rational protective reactions.

If food greatly in excess of the powers of digestion or in excess of the nutritional requirements be taken into the system, it will undergo abnormal putrefactive or fermentative processes in the bowel, with the consequent formation of abnormal and toxic products. These poisonous results of disintegration are absorbed into the portal circulation and carried to the hepatic crematorium, where, under favourable and normal conditions, they are submitted to destructive combustion. But the strain thus imposed on the liver is very apt to cause a breakdown of function, and when this occurs, these poisonous bodies escape into the general circulation, and work their fell purpose on those structures which are most susceptible to their toxic influence. The most sensitive tissues are naturally those of the nervous system. And hence in conditions of so-called intestinal toxæmia we almost invariably find extensive evidence of disturbance of nervous function. Either increased excitability with over-action, or reactionary depression with loss of function.

With excess of nitrogenous or protein foods the decomposition products are albumoses and toxins. It is these in particular which lead to the results above described. With excess of carbohydrates, we find the acid products of fermentation, lactic, acetic, propionic, succinic, and other acids, which are absorbed into the bloodstream and secure neutralisation at the expense of the circulating or fixed bases of the body. A great demand is consequently created for calcium, sodium, potassium, ammonium etc., and the tissues are thus deprived of a considerable proportion of the mineral bases they so urgently require.

With an active fermentation of carbohydrates proceeding in the bowel, the organism is in a condition of potential acidosis, that is to say, the blood would actually become acid, and extremely acid, were it not for the neutralising influence of the metallic bases. The neutral salts thus formed are excreted from the blood as rapidly as possible, but not necessarily in the urine by the renal route. They are excreted by the activity of the mucous membranes and largely found in the fæces. Under all conditions, and especially in conditions of rickets, the amount of calcium found in the fæces is extraordinarily high; as much as 25 per cent. of the dried residue of an infant's motion is often found to consist of the lime base.

The withdrawal of calcium from the system has serious consequences, quite apart from the decalcification of bone, which is one of the concomitants of mulnutrition of this kind. Calcium salts are urgently required for all growing tissues, especially nervous and muscular tissues. Consequently we can well understand that, when the system is deprived of lime, nervous symptoms and muscular debility are liable to supervene. Thus from the decomposition of excess of proteins in the bowels, we can trace a series of symptoms which are mainly referable to the toxic effects of the products of abnormal proteolysis acting on the nervous system. And from the effects of carbohydrate fermentation we find another group of symptoms, mainly those due to an acidosis and to the withdrawal of calcium and other bases from the system. In cases of injudicious feeding we sometimes find both groups in combination, and sometimes operating alternately.

The symptoms that I have described are the usual manifestations which are found in cases of rickets, and I feel convinced that the pathogenesis of this illusive disease is very closely concerned with the toxic effects of the products of decomposition and fermentation. Decomposition and fermentation may occur in the bowel from a number of different causes, chief among which are disturbances of digestion due to inappropriate or irregular feeding, and to actual or relative excess of food. If food is supplied in quantity greater than required for the physiological functions of the body it is at first stored up in the body in the form of reserve of fat or glycogen, and when the limit of storage is reached it is, as far as possible, rejected at the seat of absorption, and hence is exposed to the attacks of the intestinal flora. Exactly what constitutes excess of food and what constitutes a deficiency is a very complicated question. An active infant performing daily many muscular exercises, living in a comparatively cold environment, and not clothed too warmly, has physiological requiretments for food which are not present in an infanwhich is wrapped up in many petticoats, in which muscular movements are impeded, and which is seldom taken out of doors. Without labouring this point too much I would point out that Dr. P. Lavialle (*a*) in an exceedingly interesting series of calorimetric experiments has proved that the wearing of an ordinary bonnet effects an economy of 50 calories in the 24 hours, that is to say, an infant wearing such a protective covering to the head requires 2 ozs. of milk less than does the infant without one. Again, an infant wearing stockings effects an economy of 150 calories, or the equivalent of 5 ozs. of milk, and the infant with a shawl loses less heat by 100 calories than the one without, and consequently requires 4 ozs. less milk. Examples of this kind could be multiplied *ad infinitum*, and they suggest a number of speculations on the different requirements for food of infants differently situated. For instance, if an infant, lightly clothed, given a bath every day, taken out in the open air for many hours each day, given full opportunity for muscular exercise, stimulated by the vitalising influence of light and sunshine, requires 20 ozs. of milk in the 24 hours, how many ounces of milk should be given to an infant of similar age and weight which is wrapped in innumerable thicknesses of clothing, kept in dark, stuffy rooms, seldom taken out of doors, seldom given a bath, and hampered and impeded in all its muscular movements?

I have long pointed out that over-feeding, or rather relative over-feeding, is responsible for most of the troubles of infancy, and that it is the main ætiological factor in the production of rickets; and that a reduction in the quantity of food supplied, combined with the creation of a greater physiological demand by the stimulating influence of the graduated cold bath, and by the display of muscular activity combined with lighter clothing are the essential elements in the cure.

I have pointed out that the integrity of the reflex arc is absolutely essential for the maintenance of nutrition. I would now call your attention to the predominating influence exercised by the condition of excitability of the trophic or administrative element in this arc: namely, the nerve cell.

If the nerve cell is in a condition of normal excitability it will transfer in a perfectly normal manner to the centrifugal, trophic or motor nerves the centripetal stimuli which reach it, but if the nerve cell is in a condition of raised excitability it will magnify or exaggerate the resultant effect. On the other hand, if the cell is in a condition of lowered excitability the reverse consequences will follow.

We now know that there are constantly present in the blood a great number of internal secretions, sometimes called hormones or activators, which are capable of exercising a most remarkable selective influence on different groups of nerve cells, raising, or otherwise influencing their respective degrees of excitability. Instances of this kind at once occur to one—the internal secretion of the thyroid raises the excitability of most nerve cells, and immediately leads to a general quickening of the metabolic processes, raising the temperature, increasing the frequency of the pulse and reducing the latent period of nervous reflexes. The internal secretions of the pituitary body, the pineal gland, the adrenals and the parathyroids have still more remarkable selective affinities for various groups of nerve cells, influencing the growth and development of the body, delaying or quickening sexual development, modifying blood tension and influencing the tone of both voluntary and involuntary muscles. The influence of the internal secretion of the so-called ductless glands must now be regarded as one of the most important factors with which we have to reckon in the physiology of nutrition.

It is quite impossible for me on this occasion to enter into the details of diagnosis whereby the pathological influences of defects in these internal secretions can be recognised. All that I have been able to do is to point out that nutrition as a whole depends on a great number of different factors which are concerned with the food supply, the reception of centripetal impressions and their reflexion into centrifugal channels by the administrative intervention of the nerve cell, and that the functional capacity of the nerve cell so to transfer these impressions depends very largely on the activating influences of circulating hormones, autogenous poisons, or even foreign substances introduced from without.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal, The lecture for next week will be by Sir George H. Savage, M.D., F.R.C.P.Lond., Consulting Physician to and Lecturer on Mental Diseases, Guy's Hospital, London; Consulting Physician to Earlswood Asylum. Subject: "Post-Influenzal Neuroses and Psychoses."*

ORIGINAL PAPERS.

THE PREVENTION OF MALARIA. (*a*)

By MALCOLM WATSON, M.D.Glas.,
D.P.H. Camb.,
Chief Medical Office of the Federated Malay States Hospitals.

The author said that the miasmic and telluric theories of malaria had paralysed all efforts to eradicate the disease. It was Ross's discovery of the mosquito carrier which had pointed the way to the prevention of malaria. Successful anti-malarial work was first carried out in Klang, Federated Malay States. On arrival there as a Government surgeon, in January, 1901, the lecturer found the town full of malaria, mosquitoes and swamps, and advised Government to attempt to control the disease by a drainage scheme. This was done, and malaria at once practically disappeared. No European had contracted the disease in the town since 1901, and of 455 children examined in 1909 only 13 had enlarged spleens, all of whom gave a history of having suffered from malaria before they came to the town. In the same year a new port for the State was opened—Port Swetenham. Within 2½ months of the opening, work was practically at a standstill from malaria. The Customs, Harbour, and Railway staffs were in hospital, and the closure of the port was imminent, when the pushing forward of a drainage scheme so improved matters that in a short time the business of the port was going again with comparatively little trouble. As the land was below spring-tide level, embankments had to be thrown up round it, and the drains were closed by auto-

(*a*) Lecture delivered before the Glasgow Medico-Chururgical Society, November 7th, 1913. Specially reported for this journal.

matic valves to prevent the entrance of the sea. The net result of the drainage of these two places was to reduce the deaths by some 400 per annum.

In the same year Ross and Logan Taylor engaged in successful preventive work at Freetown, and in 1902 Ross inaugurated measures in Ismailia which brought about the disappearance of the disease there. In 1903 the publication of the lecturer's observations on malaria in rural districts led the Government to undertake the Kapar drainage scheme, embracing some 24,000 acres. There, by means of drainage and cultivation, control was obtained over malaria on the low coastal land, which was supposed to be the very stronghold of the disease on account of its stiff clay soil and high ground water. It was found that the amount of malaria bore a definite relation to the distance the population was from the breeding place of the particular mosquito which carried the disease; that the death-rate of the population was related to the amount of malaria as expressed in the spleen rate of the children; that the breeding place of the particular mosquito, *Anopheles umbrosus*, was a jungle pool; and that to abolish malaria it was only necessary to drain the pool and fell the jungle, or to remove the population away from the jungle and its pool.

While these measures were completely successful on the low coastal lands, malaria of the most malignant kind persisted among the hills, in spite of good houses on dry elevated sites, with pure water supplies and excellent sanitation. Having found that this was due to the presence of the *Anopheles maculatus*, which bred only in hill streams, the lecturer adopted the measure of carrying the streams underground in pipes for a certain distance, about half a mile, round dwellings on hill land. This was done with complete success where the full distance was piped, and marked improvement where a more restricted area only was drained. On the same lines the Government subsequently carried out an extensive subsoil drainage scheme in the Federal capital, and in 1912 the principal medical officer reported: "The results were immediate and completely satisfied the most sanguine anticipation. It may safely be claimed that general malarial infection is now non-existent within the drained area. The ravines drained have withstood satisfactory storms of great violence, and no instance of a pipe drain being washed out has occurred."

In the course of his work the lecturer found that certain rice fields or paddi swamps were free from malaria, or practically so, while others were intensely malarious, and showed that the difference was due to a difference in the species of mosquito present. It was of first-class importance to know that rice could be grown without producing malaria, and from this fact further discoveries of value were to be anticipated. There was most prospect of advance in the biochemistry of the swamp and its bearing on the larval life of the insect.

Enquiry as to how far conditions similar to those in the Federated Malay States prevailed in other parts of the world revealed the following facts. In Italy, malaria was found only in swampy places in the plains, and not at all in the hills, because there was no mosquito which could maintain its existence in hill streams. In India the conditions strongly resembled those in Malaya, and a similar explanation was now accepted. In Hong Kong the lecturer had identified a mosquito which bred in the hill streams as the same as the stream breeder in the Federated Malay States, though known locally by a different name. Malaria had always been severe in Hong Kong, and was partially overcome by "training the nullahs"—*i.e.*, by building drains with granite slabs, so that the water had a clear run down the steep hill sides. In Sumatra, across the Straits of Malacca, there was no stream-breeding mosquito, and so no hill malaria. The disease prevailed only along the coast where the swamps had not been drained. In the collection of Philippine mosquitoes in Washington the Malayan stream-breeding mosquito was not found. As regards Japan, the conditions were even more favourable than in Europe, since the only anopheles mosquito found bred in rice swamps, and carried only the two benign forms of malaria, not the subtertian malignant or æstivo-autumnal parasite found in Southern Europe.

During a recent visit to Panama the lecturer visited most of the stations of the American Sanitary Department, and studied the habits of the two chief malaria-carrying anopheles, the *A. albimanus* and *A. argyrotarsis*. Carrying on the works in what is practically jungle, with a minimum of agriculture, the Americans have overcome malaria mainly by oiling the places where the mosquitoes live. They strongly advocate drainage, but the engineering works constantly interfere with the drains. Mosquito-proof houses are used by the Americans and by some of the Spaniards, but the majority of the inhabitants are not protected. Quinine is practically not used as a prophylactic. The system of oiling, however, is perfect, the whole area for about half a mile round all dwelling places being oiled once a week so thoroughly that every mosquito is killed. The total area treated is 53 square miles. Thus in jungle, in the worst possible conditions, the Americans have built up and maintained a labour force of over fifty thousand men, whose death-rate compares favourably with that of any corresponding population even in temperate zones.

In British Guiana the inhabited portion of the country is a fringe along the coast and up the rivers, much of it having been reclaimed from the sea. Drainage, with the drain outlets protected by tide gates, and agriculture have brought about the disappearance of both *Anopheles albimanus* and *A. argyrotarsis*, and produced a fall in the incidence of malaria equal to that in Panama. Populations even live in health on the edge of rice swamps, the mosquitoes being eliminated by a proper control of the irrigation.

Barbadoes is unique among the West Indian Islands in being non-malarious, and its freedom has been attributed to the presence of the small minnows called "millions," which are supposed to eat the mosquito larvæ. The lecturer, having visted the island, believed the real explanation to be that the island is composed of a coral chalk, and is so pervious to water that no surface pools exist, and consequently there are no mosquitoes.

THE PLACE OF THE OPEN-AIR SCHOOL IN PREVENTIVE MEDICINE. (a)

By SIR GEORGE NEWMAN, M.D.,

Chief Medical Officer and Principal Assistant Secretary, Board of Education.

Sir George Newman said that at first sight there did not appear to be very much to say about open-air schools, except, perhaps, to encourage the audience to go and live in one of them, but although this was not an abstruse subject, it was one of growing importance. If they would stem the tide of physical and mental defect in the childhood of this nation, he had no doubt it would be along the lines of what he had called the open-air school process. He looked upon the open-air school not as a school held in the open air, but as a method, a process, a treatment of all education. The necessity of educating the body before attempting to educate the mind was recognised by the ancients. Plato and Aristotle referred to the value of gymnastics in the open air, not with the object of producing acrobats, but for the scientific training of the human body. The open-air ideal was characteristic of the best days of Greece and Rome. It fell into abeyance until the Renaisance period, from the middle of the seventeenth century to our own time. Sir George quoted the sayings of John Locke and Rousseau and Pestalozzi as advocating body culture before the education of the mind, and they urged that it should be carried out in the open air, and be for the normal child.

(a) Chadwick Lecture, University of London, November 11th, 1913, Sir Alfred Pearce Gould, Dean of Faculty of Medicine, in the chair.

The modern period differed from that period, in that there had been a renaisance of the idea of educating the abnormal child in the open air. That was due to different factors. (1) The growth of urbanisation of the towns, which had necessitated a different method of education. In 1870 there was a movement, which had been considerably developed in America, to get the child into the open air, and parks and open spaces were provided for children to play in. (2) The Children's Country Holiday movement began in 1878 in this country. (3) Mrs. Humphry Ward began the system of vacation schools in connection with the Passmore Edwards settlement. All these movements had helped forward the open air school movement, and no doubt some contribution had been made by the general dissatisfaction they all felt with the conditions under which many children were compelled to be educated in the schools in the large towns. Some of those schools were not ideal. Another factor which had helped the movement was the efforts to prevent tuberculosis, which had impressed the public mind with the remedial effect of the open-air treatment for consumption.

What were the evidences of a sick child, and what could they do to prevent the causes of that sickness? The first important fact was that a great mass of children died under five years of age, and the period of school life was one in which very few children died. The same applied from 15 to 55, and from that time there was, of course, a very large increase. There were four great causes of death before old age, namely tuberculosis, diarrhœa, pneumonia and heart disease, but the seeds of those diseases were sown in childhood, and were known under the names of measles, whooping cough, diphtheria, malnutrition and tuberculosis. If they were to lower the death rate from those diseases, they must turn away from the external environment of the sewerage, water supply, and housing, and deal with the personal condition of the children under school age and up to 15. Measles was responsible for the deaths of 47,000 children in one year. First they got measles, then tubercle, and then a cripple. It was no use trying to prevent disease when it was matured. They must attack it when they could grapple with it, and it must be remembered that disease in a child responded more readily to treatment than in an older person. A large proportion of these deaths from measles was preventable, or at any rate, remediable. At least 70 per cent. of those deaths ought not to have taken place. There was a great deal that the open air process could not do. It could not deal with the children under school age, but it could deal with the children of school age in five ways, namely: (1) By nipping the disease in the bud at its earliest and most incipient stage; (2) by preventing the after effects of disease which in many cases caused death or disablement; (3) by supplying the opportunity of repair; (4) by nurturing the debilitated and backward child; (5) by furnishing a new way of life for these children.

Sir George remarked that we had a large number of defective physiques in our schools, and this was, in brief, his case for the open air school process. In his succeeding two lectures on the two following Tuesdays he would show them schools which were doing effective work on the lines he had indicated.

Subsequently a number of pictures were shown by means of the lantern slides depicting the life at open air schools at Birmingham, Sheffield, Halifax, and Charlottenburg in Germany. Speaking of the open air school at Uffculme, which had been presented to the city of Birmingham by Mr. Barrow Cadbury, Sir George Newman said that the school had been constructed at considerable cost and the very best methods were being applied for the benefit of the children. There was no doubt that it was one of the best open-air schools in the whole country.

ON INDICATIONS FOR INDUCING PREMATURE LABOUR IN CASES OF EXCESSIVE VOMITING AND HEART DISEASE. (a)

By PROF. DR. ODON TUSZKAI, of Budapest.

I discussed both hyperemesis and cardiac trouble many years ago from different standpoints, and with your kind permission I will briefly now throw what light I can on the side of the question with which this Congress is concerned, and give some account of my own obervations, which are of a sufficiently interesting nature. In the first place, there can, I suppose, be no difference of opinion on the importance of conservatism among modern gynæcologists, whose most eminent representatives I have the honour to address, for we know that prescribing now one remedy and now another may minimise or even annihilate the modern boon of asepsis. In endeavouring to avoid the use of the knife by bringing our whole knowledge, experience, and mature ethical sense to bear, we must not, however, deprive sufferers of the great advantages of surgery, but must come to a definite diagnosis.

No disorders in pregnancy are more difficult to handle than excessive vomiting and heart disease, and an obstetrician is never in a more difficult position than when dealing with such cases. Some modern views on this subject only tend to perplex us. If we assume, for instance, as Hegar does, that excessive vomiting is only a symptom of hysteria, we should never be justified in interrupting pregnancy, for hysteria is a functional disease of the whole nervous system which no operation can cure. It would appear from this hypothesis that every case of hyperemesis—or at least most of them—could be cured by feigned operations, for in the cure of hysteria suggestive therapeutics play a leading *rôle*. It cannot be denied that hysteria does account for some cases of hyperemesis, and such hyperemesis hysteria can be cured or at least improved by suggestion, as for instance, by prescribing medicines with a strong smell or a pungent taste: or by imaginative treatment, such as cauterisation of the portio vaginalis, change of climate and health resort or institution; but these cases are purely hysterical and cannot be referred to the pregnancy at all, or they would not have been amenable to the treatment mentioned.

(a) Paper read before the Section of Obstetrics and Gynæcology, International Congress of Medicine, London, August, 1913.

Again, if excessive vomiting during pregnancy is only a secondary symptom of some complication of pregnancy, such as meningitis, gastric diseases, neurasthenia, peritonitis, etc., the vomiting will subside as soon as the causal complication is removed. These are cases of excessive vomiting during pregnancy, but not caused by pregnancy, and are not cases of pernicious vomiting. Finally, if we ascribe hyperemesis to intestinal toxic symptoms, though the explanation of such a condition is not quite clear, it must be explained as a disorder of metabolism which is independent of pregnancy. As hyperemesis may frequently originate in other causes than in the anatomical, physiological, or pathological conditions of pregnancy, it is clear that in such cases it would be futile to interrupt pregnancy for this condition.

Not only would it be justifiable to try every variety of treatment in these cases, but such treatment should be compulsory, because by its aid we can diagnose each individual case. Cases amenable to these therapeutic agents may be classified as cases of excessive vomiting, but not as cases of pernicious vomiting of pregnancy. From this it is evident that there is a peculiar form of vomiting due to pregnancy which can never or only very rarely be stopped as long as pregnancy continues. In my earlier writings on this subject I tried to show that the cause of this special disease was attributable to irritation of the perimetrium, through the perimetrium becoming anæmic from the pressure of the gravid uterus upon the peritoneum, either disease or other cause having lessened its power of dilating. Peritoneal irritation as the primary cause of vomiting is a recognised fact, but more physiological investigation will be required to show the causal connection beween the two. Though, as I have already said, conservative treatment would forbid surgical interference unless absolutely necessary, yet if a severe form of pernicious vomiting of pregnancy is diagnosed, pregnancy should be interrupted. What are the clinical symptoms of hyperemesis gravidarum?

1. In the first place, by the diagnostic and therapeutic measures already described every other possible cause, such as hysteric stigmata, must be excluded.

2. The diagnosis of pregnancy as a cause by local symptoms consequent on slight perimetritis, such as:

Local tenderness with increased frequency and severity of vomiting after bimanual examination: especially in cases in which the power of dilatation of the peritoneum has been lessened by a previous perimetritis. In view of such symptoms the trouble may reasonably be referred to pregnancy, but interruption of the pregnancy would not be justified until:

A. Hot or cold local applications or applications *per vaginam* have failed to bring about any improvement. This method of treatment aims at improving the blood-supply of the peritoneum and the anæmia which causes peritoneal irritation.

B. Or until wasting has gone on for a considerable time. Experience has taught me that symptoms of such a condition would be:

1. Rapid loss of weight, of the amount of urine evacuated per day, and decrease in its chlorides with a rapid decrease in the number of red blood corpuscles.

2. Increase in the specific gravity of the urine, of alkali in the blood, and increase in the pulse-rate.

3. Appearance of albumin and renal elements in the urine (kidney of pregnancy), nucleated red corpuscles and uninuclear giant corpuscles in the blood.

If in such a condition an increased dose of opium (10-15 centigrams daily) does not diminish the secretions, then premature labour should be induced without delay. By this procedure, while keeping the desirability of conservative treatment well in view, I do not hesitate, as a last resort, to interrupt pregnancy. The question of pregnancy complicated by heart disease is beset with even greater difficulty. Three or four typical cases have come under my observation, and have led to some interesting conclusions, and though I am well aware that the number of cases observed hardly justifies such important deductions, I am of opinion that these cases warrant my suggesting new ideas and obervations. "Et si licet minima componere magnis." A single skull on the strand of the Lido was enough to suggest to Goethe the interesting theory of vertebral development. A single apple falling from a tree enabled Newton to arrive at the laws of gravitation—the principles underlying modern physic. Galileo, too, only required to see a single pendulum in the Tower of Pisa to arrive at the laws of pendulum motion, and with it the motion of the earth round the sun. "Eppur si muove."

As is well known, the pulse-rate and rhythm vary when the body is in different positions, *i.e.*, it is more frequent when a patient is standing than lying down. A long time ago Graves noticed that this variation disappeared in cases of hypertrophy of the heart, and Jorissen confirmed the observation in pregnant women. Jorissen says this hypertrophy of the heart occurs in the initial stage of pregnancy, so that the disappearance of the variation in the pulse-rate may therefore be regarded as a symptom of the commencement of pregnancy. My observations go even further. In several cases of pregnant women suffering from heart disease I was able to confirm that when want of compensation began, the variation in the pulse which had previously disappeared owing to cardiac hypertrophy, reappeared again as a sign of subsequent dilatation (or as a result of dilatation). This interesting, and so far as my experience goes, new observation was of very great assistance in determining the onset of want of compensation in pregnant women suffering from heart trouble. Most authors are of opinion that it is of the utmost importance to recognise the condition at this stage, as experience shows that want of compensation usually is a serious matter in pregnancy, and accounts for many cases of sudden death during pregnancy or after delivery. Many cases complicated by disorders of the heart, even when accompanied by the gravest symptoms, go through labour without trouble, so that it was necessary to make some kind of classification of cases based on the observations of others as well as on my own, in order to provide material for investigation.

In arranging the cases in groups my pulse-symptom was of very great value: bearing in mind in each case whether the heart disease of the pregnant woman:

1. Existed before pregnancy, or

2. Whether it appeared during pregnancy, *i.e.*, as angiosclerosis or secondary phenomenon of grave latent diseases, or

3. Whether it has been caused by the pregnancy. This third is purely a hypothesis, but not an unfounded one.

Diagnosis of the first group presents no difficulty, for we usually come across advanced disease of the heart in the early stage of pregnancy, or hear of it in the past history. Prognosis is usually rather unfavourable, as pregnancy may be prejudicial to the diseased heart. Observation of the pulse-symptom I have indicated shows that normal instability disappears for a short time (the first weeks) very soon to reappear in an increased degree. Every evidence of want of compensation usually develops with this symptom sooner or later. Diagnosis of the second group does not present any difficulty provided the previous history is carefully investigated and the patient thoroughly examined. In this group the action of the pulse-symptom is as follows:—The normal instability which has disappeared owing to the normal hypertrophy of heart of pregnancy only gradually returns, usually in the second half of pregnancy, when the latent heart disease makes its ill-effects more apparent by increase in the plethora of pregnancy. An early reappearance of the instability is a most unfavourable symptom, because it indicates the outbreak of latent disease, epecially the onset of cardiac dilatation, and prognosis is unfavourable on account of the length of time the pregnancy has still to run. If the first two groups can be excluded in favour of the third and the heart trouble be attributed to pregnancy, the diagnosis is easy, and we usually find that the pulse symptom is not noticed until the later months of pregnancy and then only very slightly.

When should labour be induced, and how far does the pulse-symptom mentioned assist in forming a diagnosis? I am of opinion that, generally speaking, heart disease will rarely indicate the induction of labour, for experience shows that most of such complications do not prejudice delivery, but three important points must not be forgotten—*i.e.*:

(1) That pregnancy may be very prejudicial to a woman who already has a cardiac affection, and may indeed be the exciting cause of an early and frequently very severe complication, which may never disappear again.

(2) That no small number of pregnant women with cardiac trouble die suddenly during pregancy, labour, or the puerperium, the heart disease being the cause of death.

(3) That if disturbances of compensation have reached a certain point the induction of labour is serious and not without risk, as pregnant women with this complication are very liable to hæmorrhage, and stagnation in the blood vessels of the pelvis may occur, due to want of compensation, and it is not possible to foresee how the operation may end, as the degree of want of compensation varies according to the individual.

It is therefore of the utmost importance to examine every patient for the pulse-symptom, in order to ascertain by this sign when cardiac dilatation is beginning, as later treatment depends entirely on this phenomenon. In patients who had heart disease before pregnancy began, induction of labour will be contemplated when the instability recurs, and be carried out if improvement does not take place, which may, however, sometimes occur. The existence of this pulse-symptom warns us to be on the alert, and indicates action before it is too late: certainly earlier than has been customary hitherto. Induction of labour will be much more rarely necessary for the outbreak of heart disease which is latent during pregnancy, still when this pulse-symptom is noticed we must do all that is possible to improve the imminent want of compensation. If the instability caused by the hypertrophy of heart has persisted long and only recurs during the last weeks of pregnancy, induction of labour will probably never be thought of.

I hope that my remarks will be of assistance to obstetricians confronted by serious complications, and that my few observations will help to elucidate some questions and induce others to undertake investigation of the subject on a wider scale.

CHRONIC INTESTINAL STASIS.

By SIR ARBUTHNOT LANE, Bart., M.S.Lond., F.R.C.S.,

Senior Surgeon to Guy's Hospital and to the Hospital for Sick Children.

The following cases were shown after the delivery by Sir Arbuthnot Lane of his lecture at the North-East London Post-Graduate College on "Chronic Intestinal Stasis, which was published in our last week's issue:—

Case 1.—Miss O. M. B., æt. 40. Came under Dr. Murray Leslie's care suffering from general debility of four years' standing, accompanied by symptoms of mucous colitis with alternating constipation and diarrhœa. Had been treated with Plombiere's douches at Harrogate and elsewhere, but with no permanent benefit. There was marked yellowish brown staining of the skin, which, in association with the asthenia, suggested the possibility of Addison's disease. There was definite pain and tenderness in the left iliac fossa over the sigmoid colon. Menstruation was irregular, and the patient complained of coldness of the extremities. She had suffered from indigestion since the age of 25. An X-ray examination was made by Dr. Jordan on March 29th, 1912. There was marked dropping of the stomach and transverse colon. The duodenum was elongated; there was considerable stasis in the colon, while the cæcum appeared to be impacted in the pelvis. Cultures of Streptococcus fæcalis and of Bacillus coli were made, and a course of vaccine treatment was given, with slight general benefit but no permanent improvement. Operation on June 12th, 1912, the ileum was short-circuited into the pelvic colon. Patient had a somewhat tedious convalescence, but is now perfectly well. There is no pain, no constipation, and the patient is able to walk many miles without fatigue.

Case 2.—Miss R. B., æt. 38. Had for some months been under Dr. R. Murray Leslie's care for chronic constipation and extreme asthenia of eight years' duration, which had gradually increased in severity. Seven years before coming under observation an appendicostomy was performed, but without permanent benefit. Her physician felt that unless her condition was improved in some way, her unhappy life could not be prolonged materially by further medical treatment. In September, 1905, the large bowel was removed to the splenic flexure. She gained in weight, being 8 st. before the operation and 9 st. 4 lb. some months later. After a time the dilatation of the stomach, which had not previously been apparent, gave trouble, and in December, 1906, the pylorus was freed from the under surface of the liver. She improved for a time, but the dilatation of the stomach was soon as bad as ever. In March, 1907, gastro-enterostomy was performed, with complete relief of the stomach symptoms. After a time the descending colon and sigmoid gave trouble, and were removed in October, 1907. The patient is now (eight years after the first operation) perfectly well. There is no constipation nor abdominal discomfort, she is able to walk long distances, and can play as many as five sets of tennis without undue fatigue, and has required no medical attendance for the last two years.

Case 3.—G. H., æt. 11 (male). Tuberculous disease of hip since the age of three. Has had two operations, and has had a discharging sinus for over a year. Six months ago a large abscess was opened, swabbed out and packed with gauze. There was, on admission, three inches of shortening and marked flexion, adduction and internal rotation. He had much constipation and well-marked toxic signs. Ileo-colostomy was performed on April 28th, 1911, and marked evidence of stasis was found in the abdomen. Improvement after the operation was rapid and continuous. The hip is completely healed, and the boy is now enjoying perfect health.

Case 4.—F. M. (single), æt. 32. Laparotomy. Constipated since 1903. Every sort of medical treatment tried. In medical wards at Guy's twice. Laparotomy. Swelling of ankles and feet. Bowels open six times in five weeks while in medical wards. Abdominal pain, but toxic symptoms not very well marked. X-rays show a delay of eleven days in the transverse colon. 1909, operation. Ileo-colostomy and colectomy. Very dense bands. Cystic right ovary. Within three months of this operation she had two further operations to free adhesions. She had severe whooping cough, and in February, 1910, developed a fæcal fistula. Operation to close fistula 1912. Now doing her work as a hospital nurse. Has no discomfort of any kind, and her friends assure her that she looks ten years younger.

Case 5.—A. E. (married), æt. 30. Constipated ever since she can remember. Has been treated at five different hospitals. Severe abdominal pain for the last 18 months. Toxic signs and pigmentation well marked. Operation, ileo-colostomy, May, 1911. Abdominal pain at the beginning of 1912. On examination, patient had a tender and full cæcum. Operation, March, 1912. Colectomy. Colon found full of hard masses. Good recovery. She now feels and looks very well. Bowels quite regular every day. Eats well. No sickness. Feels much more cheerful than she has done for years. Has gained 1 st. 2 lb. Is very impressed with the difference in her hands and feet, which are now always comfortable and warm.

Case 6.—H. C., æt. 15 (male). Severe constipation needing enemata since he can remember. General health fairly good, mild toxic symptoms. Tongue very foul. X-ray examination showed a 48-hour delay in the ileum. Large masses of fæces were felt in the cæcum and ascending colon, which were only removed after five enemata. A diagnosis of idiopathic dilatation of the colon was made. Operation, June 9th, 1911. An enormously distended colon was found, together with a marked ileal kink and masses of evolutionary adhesions. Ileo-colostomy was performed, and the patient made a rapid recovery, having enjoyed excellent health ever since. He has played football during the last two winters with no ill effects.

Case 7.—A. F. (single), æt. 34. Slight constipation for the last ten years. Severe abdominal pain for the last year. Toxic signs not very well marked, but the patient has noticed the various symptoms getting worse for the last few weeks. Operation. Ileo-colostomy. (No note of what was found.) Has been very well since the operation until about August, when she began to have some pain. A further operation has been performed, and an adherent coil of small intestine freed. Patient is now perefectly well, and has no discomfort of any kind.

Case 8.—W. C. (single), æt. 24. Constipated for many years. Severe abdominal pain. Rheumatoid arthritis of both knees, which was getting worse. Wasting of right thigh. X-rays showed extreme stasis in the large bowel. Very tender over the right rectus. Slight toxic symptoms. December, 1911: Operation. Well-marked kink of the ileum and appendix. Ileo-colostomy. General health much better. Still has some pain in the knees, but the condition, according to her, has definitely ceased to progress. Bowels open daily with paraffin. Is putting on weight, and is very much brighter and more cheerful.

Case 9.—T. I., æt. 22 (male). Constipation, flatulence and heartburn for seven years. Much mental depression. For last six months attacks of severe epigastric pain and distension. A swelling under the left costal margin appeared five months ago and has increased in size. Marked toxic signs. X-ray examination showed some delay in emptying of stomach, and a stasis of 80 hours in the colon. Operation, August 8th, 1912. A large tuberculous mass was found in the omentum, to which coils of intestine were adherent. The duodenum was dilated, and there was an ileal and duodenal kink. Ileo-colostomy was performed, and within two weeks of the operation the mass in the abdomen was no longer palpable. The patient is perfectly well and at work. No abdominal or other discomfort of any kind.

Case 10.—C. F. J., æt. 56 (male). Two years ago he began to have epigastric pain after food, which was accompanied by vomiting. These attacks occurred about twice a month. Diet proved of no avail, and the attacks became more severe. During the last six months he has been losing a good deal of flesh, amounting to 2 st. in two years. Examination showed a dilated stomach and a tender ileum. X-ray examination showed pyloric stenosis, ileal obstruction, with a delay of 36 hours, and a stasis of 96 hours in the colon. Operation, March 18th, 1912. An old duodenal ulcer causing obstruction was found, and gastro-enterostomy was performed. At the same time, there being an extremely well-marked ileal kink, ileo-colostomy was done as well. Patient made an uninterrupted convalescence, and has done his work as a commercial traveller since leaving hospital without missing a day.

Case 11.—A. P. (married), æt. 54. Six years constipated. Always had indigestion. Attacks of vomiting. Severe pain in the abdomen for the last few weeks. Very pigmented. Toxic symptoms well marked. X-rays showed duodenal distension, ileal stasis. After 80 hours, bismuth had only reached the splenic flexure. Operation, August, 1912. Duodenum distended. Marked ileal kink. Ileo-colostomy. Looks twenty years younger. Feels very well. Eats well. No pain or vomiting. Is doing her work as matron of a home.

Case 12.—K. C., æt. 44. When seven years old she had a tuberculous knee, which discharged for 11 years. From 15 to 25 she was able to do a little work, but was never strong. At 25 she went abroad owing to a breakdown in health, and she had phthisis, for which she was sent to Ventnor. She had very severe diarrhœa, and when 26 had to have her eye removed on account of an old injury. She began to have severe abdominal pain, which was diagnosed as ulcerative colitis, for which she was in bed many weeks. When 29 she had severe pain in right loin, and was given a belt for movable kidney. All this time she was passing large casts of the colon. When 37 she developed a goitre, with exophthalmos, tremor and severe palpitation, which continued for four years. Two and a half years ago she had another attack of colitis, and she was in bed four months. In June, 1912, she had another attack, necessitating a long stay in bed. On admission patient weighed 7 st., and has a very tender colon. Toxic signs well marked. X-rays show very little owing to the diarrhœa. Operation, December 16th, 1912. Marked ileal kink and extensive adhesions of colon. Ileo-colostomy. Patient has made a rapid and complete recovery and has been quite well since discharge. She is able to take all kinds of exercise and to do her work.

Case 13.—K. M., æt. 44. Severe constipation since 14. Six years ago she was said to have colitis. Has had recurrent eczema, some vomiting and nausea. Much misery. Old arthritis of right knee. Toxic signs well marked. B.P. 143 m.m. Hg. X-rays showed marked colonic stasis and considerable delay in the ileum. Operation, April 15th, 1913. Ileo-colostomy. Greatly distended duodenum and ileal kink. Blood-pressure one month later was 90 m.m. Hg. This patient is now perfectly well. Her blood-pressure now, taken when she was highly excited, was 110 m.m. Hg.

Case 14.—R. W., æt. 45. Severe attacks of constipation, abdominal pain and vomiting for last two years. Much worse for last seven months, during which time she has taken no solid food. Marked pigmentation. Much complaint of coldness of hands and feet. X-rays showed a very dilated stomach and much colonic stasis. Operation, June 6th, 1913. Stomach and duodenum extremely distended. Marked ileal kink. Gastro-enterostomy and ileo-colostomy. Uninterrupted convalescence. Patient is doing her work and is in perfect health.

Case 15.—E. A. F., æt. 42. Has always been constipated, which has been more troublesome for the last three years. Severe indigestion, flatulence and epigastric pains. Some vomiting and some melæna. Has lost a stone in weight the last six months. X-rays showed pylorospasm and marked colonic stasis (80 hours). Operation, March 11th, 1913. Dilated duodenum and an appendix controlling the ileum. Ileo-colostomy. After the operation patient had pleurisy, which somewhat delayed convalescence. She is now perfectly well and has no discomfort of any kind.

Case 16.—M. H., æt. 28. Began to suffer from pain and swelling in joints when 12 years old. Had chorea when 6 and again when 17. Arthritis spread to large joints. Went to Harrogate and had baths and massage, with no benefit. Had typhoid fever when 19. Had electrical treatment and a nine months' course of Balfour treatment. No relief. Ten months ago she was curetted, and was given a course of vaccine treatment with Staph. aureus, which was obtained from her urine. She had a course of thyroid treatment, but continued to get worse. She has had considerable abdominal pain and vomiting, and has marked toxic symptoms. Finger joints stiff and in marked ulnar adduction. Knees, elbows and shoulders affected. Has not been able to sew for 18 months. Pain in joints is lessened if no protein food is taken. X-rays show a delay in colon of over 104 hours. Operation, January 3rd, 1913. Ileo-colostomy. Marked ileal kink. There was some regurgitation into the ileum, and on May 12th, 1913, a colectomy was performed. Marked improvement in the joints followed the operation, and the patient was able to sew within three weeks of the ileo-colostomy. She is now quite free from pain and spasm and is rapidly putting on weight. Her joints have quite ceased to trouble her.

Case 17.—K. H. (single), æt. 27. Constipated since birth. Has attended several different hospitals during the last eight years. She was said to have mucous colitis, and an appendicostomy was done. She had been in the habit of taking six minims of croton oil twice a week, and says this usually opened her bowels once. She has well-marked toxic symptoms and is very pigmented. X-rays showed a five days' delay in the colon. Had been bedridden for some time. Operation. Ileo-colostomy. (No note of what was found.) Looks and feels very well. Has worked as a general servant ever since her operation. Says she is greatly benefited by the operation. She is rapidly putting on weight.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

TWO CASES OF RUPTURED URETHRA.—MR. ARTHUR EDMUNDS operated on a boy, æt. 11, who had been admitted with the history that he had been trying to walk on the edge of a railing in the park. He slipped and came down astride the top bar. A catheter was passed to apparently full length, but only a little blood was withdrawn. Thirty-six hours after the accident he was admitted to the hospital. He had not passed any urine, the pudenda were enormously swollen, the scrotum being the size of a baby's head, and there was œdema of the lower segment of the abdominal wall. He was anæsthetised, and three incisions were made into the abdominal wall and one on each side of the scrotum. The fluid was squeezed out as far as possible, and then a median incision was made in the perineum, which was deepened until a mass of extravasated blood was reached. This was then turned out and a bougie passed through the meatus emerging into the perineal opening. The upper vesical end of the urethra was then sought for and, after some little difficulty, discovered. The bougie was then removed and No. 8 Jaque's catheter introduced, brought out through the perineal wound, and then passed into the bladder. The urethra was then carefully sutured round the instrument. The wounds in the abdominal wall were packed lightly with gauze, a drainage tube was inserted into the scrotal wound, the perineal wound was lightly packed, and the patient sent back to bed. Four days later the abdominal wounds were sutured and healed by first intention, the swelling having completely subsided. The boy did well, although at one time there was a slight leakage from the perineal wound, but only for a few days. The catheter was removed at the end of a week, and the patient micturated normally. On one occasion he had retention for twelve hours, but this was only spasmodic; a full-sized instrument passing easily. About six weeks after the accident he again had retention, partly due to contraction, but mainly to spasm. Instruments were passed with a little difficulty, and the boy is now micturating normally.

The second case was that of a boy, æt. 5, who was admitted with a history that he had been climbing on a railing and had fallen down in a sitting position, striking his perineum on the ground. He was brought to the hospital immediately, when it was found a catheter could not be passed beyond a short distance, no urine being obtained, but a considerable amount of blood escaped. The operation was conducted as in the previous case except that, as no extravasation had taken place, it was not necessary to make any incisions into the scrotum or into the abdominal wall. Ten days after the operation the boy was doing well.

These cases, Mr. Edmunds said, show the value of an early diagnosis, but this is less important in young children where the rupture is due to an injury than in adults where it is due to the rupture of the urethra behind a stricture, inasmuch as if the urine is aseptic there is not the same risk of cellulitis, and it is often possible, as in one of the present cases, to suture the incisions.

These two cases make an interesting comparison with the case by the same surgeon published in "Operating Theatres" on August 27th.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

MEETING HELD NOVEMBER 6TH, 1913.

The President, DR. W. S. A. GRIFFITH, in the Chair.

SPECIAL DISCUSSION ON THE RELATION OF THE INTERNAL SECRETIONS TO THE FEMALE CHARACTERISTICS AND FUNCTIONS IN HEALTH AND DISEASE.

THE complete paper, introduced by W. BLAIR BELL, M.D., was distributed beforehand, and will be published in full in the *Proceedings of the Royal Society of Medicine.*

Allusion was made by the introducer of the discussion to the great advances which have been made during recent years in the science of gynæcology and obstetrics. After pointing out that from a broad standpoint femininity itself is entirely dependent on the internal secretions acting in correlation, he considered the more purely morphological and physiological aspects of the subject. The production of the female characteristics—primary and secondary—were traced to the internal secretions, and facts were quoted in support of the statements made. It was shown, too, how the internal secretions directly and through the general metabolism initiated the genital functions at puberty. By way of illustration the calcium metabolism was described in its bearing on the question under discussion.

Next, the maintenance of the female characteristics and functions were dealt with, and experimental evidence was given of the importance of all the internal secretions in effecting this end.

The conclusions in regard to the morphological and physiological aspects of the subject were:—

(1) The development and integrity of the genital organs and their functions are dependent on all the internal secretions, individually or collectively.

(2) The removal of any one organ of internal secretion produces changes in the others, and by this means we gain some insight into the existing correlations.

(3) The general metabolism is altered by extirpation of any of these organs. This alteration in the general metabolism affects the genital metabolism.

From physiological and morphological investigations we have obtained the following information which may be emplyed in the solution of clinical problems:—

(1) Our knowledge of the influence of the internal secretions on the sex characteristics and on the development of the genitalia helps us to understand the pathology of hitherto obscure conditions connected with sex characteristics and the development of the reproductive organs. So, also, can we trace the influence of the internal secretions on the psychology of our patients, for in women femininity is associated with psychical qualities which need not be defined here. These qualities are due to the combined action on the brain cells of the metabolic conditions produced by the feminine organs of internal secretion; and the normal psychical condition is frequently disturbed by pathological conditions of the endocrinous glands.

(2) Since we know something of the influence of the internal secretions on normal menstruation we can note the abnormal effects produced in regard to the menstrual function, and conversely we can observe the effects produced on the organs of internal secretion by local derangements of the genital organs.

(3) Knowing, also, the part played by the internal secretions in the metabolism of pregnancy, we can, in the same way, observe the effects of deviation from the normal.

The second part of the introductory paper dealt with pathological and therapeutical considerations.

First, derangements in the development of the genital organs and their functions were discussed under the following headings:—

(1) Imperfect and irregular primary development of the genitalia.

(2) Irregular secondary development of the female genitalia and functions.

It was shown under the first heading how pseudo-hermaphroditism might be produced, especially by hyperplasia of the suprarenal cortex. And under the second heading it was demonstrated how the onset of puberty (precocious or delayed) was under the influence of the organs of internal secretion.

Next, derangements of the fully established female characteristics and functions were discussed.

This part of the subject was dealt with at some length, since it was of considerable interest from a clinical point of view. The derangements of the fully developed sexual characteristics first came under notice. Then the derangements of the fully established functions were considered from the points of view of increased and decreased secretion from each special organ. Many clinical phenomena in connection with menstruation and pregnancy were discussed in detail.

The results of experimental investigations of the metabolism of animals after partial or complete removal of the different ductless glands were demonstrated by means of tables; and a series of photomicrographs were shown to illustrate the structural effects produced on the other organs of internal secretion after the partial or complete removal of one of the members of the endocrinous system.

Dr. Blair Bell was followed by Miss Louise McIlroy, M.D., who had been specially invited to continue the discussion. The speaker (whose paper will be published in full in the *Proceedings of the Royal Society of Medicine)* considered the subject under the following headings:—

(1) The importance of comparisons between the results of experimental work upon laboratory animals and clinical observations. Examples.

(2) The influence of the internal secretory organs upon development.

(3) The constituents of the ovary and their function.

(4) The necessity for clinical records upon the effects of oöphorectomy before puberty, during reproductive life, and during pregnancy.

(5) The effects of oöphorectomy alone as compared with oöphorectomy combined with complete hysterectomy. Influence of uterine secretion.

(6) The clinical aspect of ovarian transplantation.

(7) The influence of ovarian secretion upon metabolism, lactation, and the other internal secretory organs.

(8) The influence of the internal secretory organs upon disorders of menstruation, with special reference to precocious menstruation, menorrhagia of puberty, and early menopause.

(9) The treatment of gynæcological conditions by glandular extracts. Examples.

(10) The relationship between general toxæmias and derangements of the internal secretory organs.

Miss Louise McIlroy thought it a happy augury for future work that there should be so much collaboration between the laboratory worker and the clinician. Much confusion as to the function of the ductless glands arose from want of proper comparison of the variations in different species of animals and of the human individual. The secretory organs modified sex development, but did not cause the assumption of secondary characteristics, as these will probably be found to be due to cell development in very early embryonic life. The effects of oöphorectomy alone as compared with combined hysterectomy were mentioned, and the influence of the uterine mucosa discussed, the clinical aspect of ovarian transplantation, the influence of ovarian secretion upon metabolism, and upon menstruation in correlation with the other internal secretory organs were brought forward. Treatment of menopausal symptoms by ovarian and mammary extracts, and menorrhagia by pituitary extract by the mouth gave encouraging results. The influence of the thyroid gland upon toxic conditions was a subject of great importance in gynæcological and obstetrical conditions.

The two papers led to a very interesting discussion, in which many invited speakers took part. Among these were the President, Professor. F. H. A. Marshall, Dr. T. R. Elliott, Mr. James Berry, Dr. Leonard Williams, Dr. R. Murray Leslie, Dr. Florence A. Stoney, Dr. Amand Routh, and Dr. H. R. Harrower.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting Held at the West London Hospital,
Friday, November 7th, 1913.

Clinical Evening.

The President, Dr. F. S. Palmer, showed a case of "pseudo-hypertrophic paralysis." Patient, æt. 7, the elder of two children, both boys. Began to walk at 2 years of age, but was unsteady on his legs and fell frequently. Always had great difficulty in ascending stairs. No history of familial nervous disease on either side, but a younger brother, æt. 6, is similarly affected. He presents all the characteristic features of the disease.

Case of "morbus cordis and hemiplegia." Female, æt. 22. Has always been blue as long as she can remember. Shortness of breath on the least exertion. Acute rheumatism at 17, and second attack at 19. Hemiplegia, sudden onset on the left side in March, 1912. This gradually cleared up. Her colour is remarkable from the degree of cyanosis and the clubbing of her fingers and toes is most marked. The cardiac area is still increased H.A.B. in the fifth space in the nipple line. Loud harsh bruit over the pulmonary orifice (systolic) conducted upwards and to the left. Double mitral bruit at apex, traced outwards to the axillary line. Loud aortic double bruit heard at the third right costal cartilage.

Dr. Arthur Saunders and Dr. Morton: Six cases of "early pulmonary tuberculosis in children" between the ages of 5 and 10. These cases show no physical signs on examination of the lungs, but present the following symptoms: Wasting, irritable cough and night sweats. Dr. Morton's skiagrams show very clearly enlargement of the glands at the root of the lung, and also a greater or less invasion of the root of the lung itself in every case.

Case of "congenital syphilis," shown by Dr. Russell Steele for Dr. Arthur Saunders. Child, æt. 12. Symmetrical swelling of the knee-joints. History of a rash on arms, legs and buttocks lasting three months, one year ago. Mother gives positive Wassermann. Patient is an anæmic boy, shows symmetrical swelling both knee joints, the swelling being chiefly fluid in nature. No signs of interstitial keratitis, no other obvious signs of syphilis. Wassermann strongly positive. ·45 gramme neo-salvarsan given intravenously on October 16th. No improvement has occurred.

CAPILLARY DILATATION.

Dr. Saunders: Congenital dilatation of capillaries in a child, æt. 7. Exaggerated mottling of the skin present from birth. Most marked over the malar regions, the extensor surfaces of the forearms and hands, and the flexor surfaces of the buttocks, backs of the thighs, and legs. Over the right buttock there is a line of about one finger's breadth of normal skin. There is no cardiac lesion discoverable. The hands are usually rather cold, and become cyanosed when exposed to the cold.

Dr. F. S. Palmer remarked that this case of capillary dilatation was the most remarkable he had seen. The appearance of these vascular patches suggests something between so-called port-wine stains and a modified form of Raynaud's disease. The skiagrams of early pulmonary tuberculosis in children, as exhibited, are very interesting and show the extreme importance of X-ray work in the diagnosis of early pulmonary tuberculosis in these young subjects.

Mr. Aslett Baldwin: Case of

TRAUMATIC ASPHYXIA, AND HÆMORRHAGE

into the cervical cord. Patient, æt. 26, was admitted on October 28th, having been crushed between a lift and a balance weight. He was unconscious, breathing laboriously, pulse very weak. Several ribs on the left side were broken, and there was an enormous degree of surgical emphysema, on the left side of chest, abdomen and back. His pupils were dilated and very sluggish and his colour very blue. On the 29th, he began to regain consciousness, but the emphysema continued to spread. His sputum was slightly blood-stained. On the 30th, he regained consciousness, the emphysema was disappearing, and there was much muco-purulent sputum tinged with blood. As the general blueness disappeared it was apparent that there was a permanent blueness of the skin of the face and neck, and also hæmorrhages into the conjunctivæ of both eyes. There is marked weakness and loss of reflexes in all the muscles supplied from the brachial plexus. This, he thought, was due to minute hæmorrhages into the cervical cord. The case is improving rapidly, and complete recovery should take place.

"Implantation of rib to replace loss of bone due to compound comminuted fracture of tibia and fibula." The patient sustained a compound fracture of the tibia and fibula, leaving ultimately a gap of about 4 ins. between the two ends of the bone. A piece of rib was grafted into this space and X-rays show that the bone has united to both ends of the tibia. The operation was done about 16 days ago, and new bone formation has already occurred.

Dr. Ogier Ward remarked that the case of traumatic asphyxia is opportune. The daily papers, he said, are busy discussing euthanasia in apparently hopeless cases. This patient recovered, though in the opinion of competent men he had not an hour to live. Doubtless he suffered intensely, and if once the principle of euthanasia were admitted his case would surely have been held to justify an over-dose of morphia.

Mr. Bishop Harman exhibited cases of "syphilitic uveitis."."

MORBUS CORDIS.

Dr. Harold Pritchard showed two cases of morbus cordis, both having well-marked valvular lesions, the results of acute rheumatism. Fever was present in both cases and in both bacteriological examination of the blood showed the presence of a short chain streptococcus. When first seen the two cases were thus clinically identical. The one proved to be a true case of infective endocarditis, with fever, anæmia, wasting, sweating, and the presence of arterial emboli, the patient going steadily downhill. The other case proved to be one of simple endocarditis with pulmonary emboli, the positive blood culture being presumably due to a transitory infection of the blood stream. These two cases are illustrative of the difficulty of diagnosis in the early stages between simple and infective endocarditis. They also emphasise the value of blood culture and the extreme importance of combining clinical observations with the bacteriological findings.

Dr. F. S. Palmer remarked that there were some points of resemblance in the clinical history of this case and the later developments in the case of congenital heart disease he showed. In such cases there is always the fear of septic infection. In his experience of malignant endocarditis, neither serum nor vaccine therapy had been of any use, and though he had seen them go on for months the termination has always been fatal.

Dr. Grainger Stewart showed a case of "syphilitic disease of the cervical spine" with sensory symptoms referred to the distribution of the upper cervical root areas. Patient, æt. 45. Syphilis seven years ago not treated. Eighteen months ago, fell from a cart on the back of his head. Felt pain in the neck for a few days. For the last 12 months pain gradually developing in the upper cervical areas of the left side. On examination, the area of pain is found to extend from the distribution of the fourth cervical areas to that of the fifth cervical nerves, and over this area there is diminished sensibility to all forms of cutaneous sensation. There is no evidence of any implication of the spinal cord. X-ray examination shows changes in the upper cervical spine, some destruction of the bodies of the vertebræ, and considerable overgrowth and new formation. Wassermann strongly positive.

Dr. Stewart also exhibited a case of "Toxic polyneuritis affecting specially the lower motor neurone," in a girl, æt. 17, in whom there was no constitutional disturbance and no evidence of arsenical lead or alcoholic poisoning. All deep reflexes in arms and legs were abolished. Superficial, epigastric and abdominal diminished. Plantar, flexor. Marked loss of sensibility to all forms of cutaneous sensation in the distal portion of the limbs with some loss of sense of position. General state good. Wassermann reaction of blood and cerebro-spinal fluid negative. Culture from cerebro-spinal fluid negative.

Mr. Oswald L. Addison showed a case of "Syphilitic osteo-periostitis," in a little girl. Also a case of "Abdominal tuberculosis," in a boy, æt. 13, who was admitted to the Hospital for Sick Children, Great Ormond Street. And a third case of

ACUTE APPENDICITIS AND GENERAL PERITONITIS

in a boy, æt. 7, was admitted to the hospital desperately ill, almost comatose. Under spinal anæsthesia the abdomen was opened, the gangrenous appendix removed, and tubes placed in the right iliac fossa and the right and left hypochondriac regions. For the first few days it seemed impossible that the patient could recover, two attacks of cardiac failure on the second day proving nearly fatal. The condition gradually improved, and the temperature came down, but on the 20th a residual abscess of the left iliac fossa was opened. A day or two later the whole of the left lung became solid and the temperature ranged between 104 and 102, gradually falling till it reached about normal on the 29th. During this attack of pneumonia, the original wound, which had been bathed in pus from the time of the first operation, gave way, and some coils of small intestine prolapsed owing to the constant cough. On July 1st, the bowel gave way, and by the 5th the opening had become so large that the greater part of the intestinal contents were being discharged over the skin of the abdomen. On the 5th, the partially prolapsed bowel was separated from the margins of the wound, and with great difficulty about 12 ins. of badly-damaged intestine was resected, and a lateral anastomosis performed. The temperature gradually fell to normal, and the patient took his food well, but was wasted to an extreme degree. The abdomen was flat and the patient had no pain, but some cough still persisted. Empyema had been suspected, and a careful watch had been kept. An exploration on one or more occasions proved negative. A fortnight after the enterectomy was done a fæcal fistula again formed, the wound having almost healed. As the fistula enlarged a second enterectomy was performed with the greatest difficulty. At the same time the chest was explored once more and about 1½ pints of pus were evacuated. Convalescence after this was very slow, but improvement gradually occurred, but ultimately the patient was able to leave the hospital, nearly three months after the commencement of the illness. The vitality of the child was simply amazing; even on admission to the hospital it seemed impossible that the child could live for more than a hour or two. All the operations, with one exception, were performed under spinal anæsthesia, and he was quite certain that the patient would have succumbed to any of the operations had a general anæsthetic been used. He attributed the recovery of this patient to the continuous use of saline solution per rectum, subcutaneously and intravenously, combined with the most unremitting care and attention on the part of the house surgeon and the nursing staff.

Mr. Tyrrell Gray showed three cases: (1) "Sarcoma of a keloid of the eyebrow; (2) case of "Implantation dermoid following circumcision"; (3) case of (?) "Sarcoma of the maxilla," in a boy, æt. 10.

Dr. Firth showed a man, æt. 32, with marked scoliosis of the lower cervical vertebræ. The condition has been present since birth. X-rays shows a wedge-shaped extra vertebra in the lower cervical region.

THE HARVEIAN SOCIETY OF LONDON.

Meeting held on November 6th, 1913.

Dr. Leonard Guthrie in the Chair.

Mr. Eric Gauntlett read a paper on

FRACTURES ABOUT THE ELBOW-JOINT.

The author remarked that fractures around the elbow-joint are divided into those affecting the lower end of the humerus, of which the transverse supracondyloid, the T- or Y-shaped intercondyloid, fracture of either condyle, and separation of the epiphysis are the most important, and those affecting the radius or ulna, amongst which fractures of the olecranon, coronoid, and the head of the radius are commonest. Accurate diagnosis is of the greatest importance, and in children particularly. General anæsthesia is often necessary for this purpose. Skiagraphy, although useful in cases with obvious displacement, may be most misleading in less serious injuries. Diagnosis depends on an accurate comparison of the two limbs, with special regard to the position of bony points, measurements and abnormal mobility. The various varieties of these fractures were then discussed in detail. In treatment all these fractures, with the exception of those affecting the olecranon, are best treated by full flexion, and operative interference is seldom called for, except in the case of those T-shaped fractures involving the joint. Massage should be commenced early, and passive movement at the end of the first week. The latter should be gentle, so as to avoid all unnecessary movements of the fragments. Finally, all doubtful injuries to the elbow in children suggesting an injury to the epiphysis are best treated in this manner, although the physical signs may be indefinite.

Dr. Percy Ridge read a paper on

THE PECULIAR CHARACTERISTICS OF TUBERCULOUS SPUTA.

His paper was based on valuable research work carried out on upwards of 2,000 cases, in which the albumin content and the cytological aspect had been obtained in each case. From this investigation he was able to draw conclusions, helpful both in the diagnosis and prognosis of tuberculous lesions of the lung. Wide interest was taken in the paper.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, November 6th, 1913.

The President, Mr. Robert Jones, F.R.C.S., in the Chair.

Dr. C. J. Macalister read a note on the "Treatment of Emphysema." He had noticed that in these patients the main difficulty was in expiration. He had successfully aided the expiratory forces by a band of strong elastic webbing round the chest. He showed two, patients, one a child and the other an adult male in whom the condition had been greatly relieved. The application was not used in cases where much bronchitis was present.

Dr. R. W. Buchan, Dr. S. McLellan and Dr. McAfee spoke, and Dr. Macalister replied.

Sir Dyce Duckworth read a paper on

SOME REQUIREMENTS FOR MODERN CLINICAL TEACHING.

While admitting that no intelligent member of the profession could ignore the assistance rendered by the purely scientific research worker in bacteriology, in bio-chemistry and physiology, it was still necessary to regard the practice of medicine as empirical—it was the product of experience founded upon observation. The want of the present day was training in accurate observation. He thought the old teaching in botany and the allied sciences gave a certain preparatory training in observation that had its value. He thought the scientific training to-day was pushing into too small a space the necessary clinical training and experience. In this country we had perhaps less of scientific methods in medicine, but he was sure foreign schools might copy us in the greater humanity of treating and nursing the sick. Sir Dyce Duckworth spoke of the need for training in the lost art of physiognomical diagnosis; the humoral personality of Ch. Richet was closely allied to the old diathesis, and could give a clue to many problems in clinical medicine. In treatment clinical observation must be the final court of appeal. The inherent vitality of some individuals, and even of some races, such as the Hebrew, if forgotten would lead the physician to give a gloomy prognosis and so provide triumphs for the faith and spiritual healers. Anæsthesia, anodynes, and the press of modern life had much to answer for in the over-tenderness, introspection and mawkish sentimentality seen to-day. The recommendation that we should adopt the German ideals of teachers of clinical medicine debarred all private practice and would lead to a limited outlook. The scientific staff of the training school would also need adequate remuneration, and the whole scheme was not likely to produce such good practitioners as our present plan. The object of medical education was not to pass students through examinations but to prepare them to be useful practitioners. The teacher must be human and sympathetic, not looking upon patients as mere cases. He must teach manners, he must believe in his art and pursue it with tact, common sense and genial regard for his fellow human beings, trusting to well tried methods and not running after every novelty. In being himself dignified he should dignify his profession.

Dr. T. R. Bradshaw spoke of the practical difficulties of putting all a student's clinical training into two years, which was far too short a time in which to cram all that had to be acquired. He spoke of the value of purely scientific treatment and instanced diphtheria. He also mentioned Sydenham's ideas of the constitution of fevers as an example of empirical ideas which had not proved to be of value.

Dr. R. Caton also spoke of the large amount required of the student. Six-and-a-half years was required, and yet it was proposed to further add to it.

Sir James Barr, Professor E. Glynn, Mr. Newbolt, Dr. Bennett, and Dr. R. J. M. Buchanan took part in the discussion, and Sir Dyce Duckworth replied.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held on November 7th, 1913.

The President, Mr. A. Ernest Maylard, in the Chair.

A lecture, with lantern demonstration, on

THE PREVENTION OF MALARIA

was delivered by Dr. Malcolm Watson, Chief Medical Officer, Estates Hospitals Association, Klang, and member of the Malaria Advisory Board, Federated Malay States. This lecture will be found in another column, under the heading of "Original Papers."

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 15th, 1913.

Chlorate of Magnesia.

Chlorate of magnesia is non-toxic at the dose of 30 grains a day; it can be prescribed for months and years provided that laxatives are given from time to time, as the drug is astringent. It produces no irritation of the stomach, it is slightly vaso-constrictor, decongestionates the mucous membrane of the nose, hence its favourable action on coryza.

At the dose of 15 gr. taken twice at day, in a wine-glass of water, chlorate of magnesia provokes absorption of neoplasms. During the first two weeks the tumour seems to increase rather in size, but resorption soon begins and continues for weeks and months until the tumour disappears, but to avoid relapse the treatment should be continued for nearly two years. Chlorate of magnesia has no nocive action on the organism; it would seem rather to develop the memory and the intelligence of the individual.

For coryza it acts like a charm. Ten grains taken in water before the morning and mid-day meals, and a similar dose the following morning, or three doses in all, suffice to cure that troublesome affection popularly known as a cold in the head. Even one hour after the first dose a considerable improvement is observed.

FALLING HAIR.

Rub into the scalp each night for a week—

Precipitated sulphur, 5 dr.
Proof spirit, 6 oz.
Ess of lavender, x. min.

The next week the following solution is employed:-

Tincture of iodine, 1 oz.
Proof spirit, 7 oz.

Suspend for another week and recommence the treatment. The sulphur lotion arrests the itching and stimulates the skin. The alcoholic solution of iodine removes all the parasites (microbian) from the head and acts as a disinfectant. No glycerine should be added to either of the mixtures. The treatment is easy to follow and is unnoticed by the lay writers.

PRURITUS.

The internal symptomatic treatment of the different varieties of pruritus consists in the employment of sedatives of the nervous system, particularly such drugs as bromides and valerian.

Attention should be paid to the possible cause of the affection—parasites, diabetes, gastro-intestinal troubles (frequent cause), dyscrasia and diathesis. For this latter a severe *régime* should be prescribed, suppression of stimulants and fermentable foods—vegetarian *régime* in a word. Many rebellious cases of pruritus have yielded to a purely milk diet.

The patient will be recommended to live as much as possible in the open air, to use the morning tub and dry rubbing of the skin to stimulate its function. No flannel will be worn next the skin.

Pruritus of the Vulva.—The cause may be one of ovarian insufficiency: dysmenorrhœa, menopause, requiring ovarian opotherapy. Want of cleanliness, especially in stout women, prolapsus uteri, and above all leucorrhœa.

The treatment consists in lotions with corrosive sublimate or chloral, followed by dusting with—

Talc, 1 oz.
Camphor, ½ dr.
Starch, 1 oz.
Ess. of geranium, x. min.

In many cases a more active treatment may be required—application of a solution of nitrate of silver (1-100), or an ointment of ichthyol (1-10), while vaginal suppositories are inserted at night—

Cocaine, ½ gr.
Ichthyol, 5 gr.
Cacao butter, 1 dr.

Pruritus of the Anus.—

Nitrate of silver, 6 gr.
Distilled water, 1 oz.

Paint the region each evening. After each application the following ointment is applied:—

Ichthyol, 20 gr.
Oxide of zinc, 1 dr.
Vaseline, 5 dr.

After which the parts are powdered with—

Oxide of zinc, 1 oz.
Camphor, 20 gr.
Talc, 2 oz.

TUBEROUS ABSCESSES OF THE AXILLA.

These abscesses are very frequent, and in certain subjects return continually. Their cause is the same as that of boils—staphylococcus. Certain predisposing conditions favour their development, such as itching, sweat softening the epiderm, want of cleanliness, and also a certain disposition of the individual.

When the pus is formed a small incision with the bistoury should be made, the region being previously shaven. The thermo- or galvano-cautery should replace the lancet when possible.

After the incision the region is sprayed with some antiseptic solution, as for anthrax, a moist dressing is applied, and the patient returns to his occupation. Tincture of iodine is employed in the day time and the following pomade at night:—

Aristol, 20 gr.
Baume de Peru, 1 dr.
Stovaine, 1 gr.
Vaseline, 5 dr.

The general treatment consists of cod-liver oil, iron or arsenic.

GERMANY.

Berlin, Nov. 15th, 1913.

At the Hufeland Society Hr. Ad. Czerny showed a case of

CHRONIC PNEUMONIA IN AN INFANT.

The infant was of healthy parentage, and was æt. 10 months. The illness which was to be described dated from the seventh month. Four weeks previously a brother of the little one, who was two years older, began with whooping-cough. The illness of the infant began with high fever and cough and to all appearance it was whooping-cough also. The patient was admitted into hospital three months ago at the commencement of the illness. The condition then was very threatening. There was fever, the alæ nasi worked with the respirations, increase in size of the lungs, the ribs were strongly drawn in at the interspaces during inspiration, as also the supraclavicular spaces. Respirations were increased 72 per minute. On auscultation only a few rhonchi were to be heard at the front, but abundance of crepitant sounds, both at back and sides. There was no circumscript or absolute dulness, no bronchial breathing. The cardiac sounds were gentle and not sharp. Meteorism, the liver greatly enlarged.

The symptoms appear to justify a diagnosis of bronchopneumonia of both lungs, and especially spread over the posterior portions. The child coughed in a marked manner, but the cough had not the characteristics of whooping-cough.

Under a line of treatment that was on the whole stimulating the general condition of the patient improved slowly. The circulatory disturbances improved, as shown by the disappearance of the meteorism, diminution of the liver enlargement and relief of the dyspnœa. The fever continued for eight weeks with considerable oscillations in the range of temperature. The cough, however, was not gone even yet. Now that the fever had subsided the general condition was improving more rapidly. An interesting feature of the case was that a symptom still persisted that had been present throughout the whole of the illness, *i.e.*, the whole of the three months. Râles were to be heard over both lungs, behind from above and to below, but they had not the crepitant character of the first stages of the disease. There was no telling how long these râles would continue. The speaker would not be surprised if they still continued for some months. Every case of chronic disease of the lungs demanded that tubercle should be excluded. In his case the cutaneous test was negative and no bacilli had ever been found in the sputum. When such a case succumbed to the disease or to any intercurrent affection numerous bronchiectases were found to have been the cause, or perhaps to speak more correctly, numerous small cavities in the lungs. According to the investigations of Vogt they were most frequently associated with infection from the influenza bacillus. We knew further that the influenza bacillus was frequently found as a complication in whooping-cough and measles. As an infection most likely passed from one brother to the other, and as the brother had the whooping-cough it was most likely that the case had that pathogenesis. The formation of the little cavities in the lungs must not be put down to any special kind of bacterium. Influenza infections were very frequent in children. but only individual children acquired these cavities. It would almost seem as if there must be some anatomical predisposition. In favour of this assumption was the fact that this development was sometimes met with several times in one family. In such families several children died in a year one after another from pneumonia.

There were three points that should be mentioned. He had said the patient had been infected from a case of whooping-cough, but he had no whooping-cough, only a pronounced disease of the lungs. The brother's whooping-cough was certain. The occurrence of various forms of disease from the same infection was not a rarity. It only showed that for the occurrence of typical whooping-cough several factors must work together, which in the case related were not all present. Secondly, it appeared to him that X-ray examination was useful for diagnostic purposes in such a case. If the bronchiectasis was not accompanied by bronchopneumonia use of the rays would be negative. That was so in the case of the child. The negative result of an X-ray examination did good service in differentiating tuberculosis and the residua of chronic pneumonia from bronchiectasis. The third and last point related to treatment. From clinical observation we learned that such cases did recover, if only slowly. Whether such a recovery was anatomical admitted of doubt. As regarded the dilatation alone recovery might well be assumed, but recovery must be doubtful as far as the cavities in the lung were concerned. Of all the methods of treatment in vogue in such cases he must mention as valuable above all the so-called thirst treatment. A limitation of liquid in the food until the urine passed did not much exceed 100 c.cm., had a pronounced effect on the exudation from the lungs. By this we attained the disappearance of symptoms, and if continued long enough recovery took place so far as anatomical recovery was possible. With children beyond the infant stage the treatment could be carried as strictly and with the like results as in adults, but in the case of the infant the liquid could not be so strictly limited as in later age. The results of such withholding of liquids were not so marked as in the adult. The requirements of the infant were not, however, a contra-indication for the treatment. Even in such a case as the one under discussion the liquids should be limited as much as possible.

Hr. Ewald remarked that the case threw a light on the origination of cases of severe bronchiectasis in older children where the disease came on suddenly and without any obvious cause.

AUSTRIA.

Vienna, Nov. 15th, 1913.

Resection of Joints.

At the recent meeting of the K.k. Gesellschaft der Aerzte in Vienna, Dr. Alfred Exner exhibited a woman, æt. 27, on whom he had operated for ankylosis of the left elbow-joint. She was a hairdresser, and has suffered in 1911 from very acute rheumatism of the principal joints of the limbs. With careful, prolonged treatment, the other joints were completely restored, but the left elbow was completely ankylosed, so that the power of pronation and supination was entirely lost, as well as that of flexion and extension. The parts were exposed by bilateral vertical incisions, the ends of all three bones resected to a depth of about a quarter-centimetre, and the capsule completely extirpated, according to Payer's method. After wrapping the end of the humerus in flaps formed from the fascia lata, the bones were replaced, the wounds sutured, and the arm kept rigidly fixed for a week. Passive motion was then commenced, and with a perfect result. All the normal movements of the elbow-joint are now performed with ease and the patient follows her vocasion as before.

In the discussion which followed, Dr. O. Föderl stated that for the past twenty years he had, on the ground of results obtained from experiments on lower animals, made use of the bladders of swine and ovarian cyst walls in the construction of artificial joints after resection for osseous ankylosis; after impregnation with paraffin for the purpose of diminishing susceptibility to absorption. The fascia lata was a very suitable structure for this purpose; but it can here fulfil no other purpose than separation of the ends of the resected bones and providing for the permanence of the articular fissure. The ends of the resected bones require careful covering to the extent to which they are normally invested by the articular cartilage. And, as the soft parts around the joint retract after the operation, it is desirable that the osseous extremities should be invested with a material which strongly resists absorption, so far as the normal articular pocket extended in all directions.

Treatment of Trigeminal Neuralgia.

Dr. Julius Flesch described the results obtained by the treatment of trigeminal neuralgia with alcohol injections in over 80 cases. This method is effective in idiopathic trigeminal neuralgia—true tic douloureux—to a more satisfactory degree than that of peripheral or deep extracranial nerve-resection. In Härtel's treatment by injection of the ganglion, we have a procedure which proves to be almost as effective as extirpation of that structure. Accordingly, in every refractory case of severe prosopalgia, after failure of internal medicaments and external applications, the procedure of alcoholic injection—peripheral, deep, or intraganglionic, may be adopted; and it is only when all these have failed to give the desired result that Krause's extirpation can be rightfully resorted to.

Dr. J. Pal recommended more frequent trial of the much milder procedure of treatment with the Leduc current. Animals can be narcotised by the Leduc current, as Dr. Pal had himself demonstrated. Leduc had narcotised himself with his own current. Dr. Pal had to thank its adoption for many very satisfactory results.

Dr. J. Tein referred to other therapeutic applications of alcoholic injection which gave excellent results, but were not generally known or estimated at their true value. An example was that of severe laryngeal tuberculosis, in which the patient was unable to swallow from the intense pain. After an injection of alcohol has been made, the patient can, as a rule, swallow almost without pain in a few minutes; and the pain is frequently removed for some days, or, at least, greatly diminished. The injection can be repeated after an interval of some days. The needle is introduced, from without, between the os linguæ and the superior margin of the thyroid cartilage, so as to reach the superior laryngeal nerve.

Dr. M. Grossmann referred to the not infrequently brilliant results obtained in the treatment of tic douloureux by galvanic cauterisation of the individual turbinated bones. It may, indeed, be that centripetal stimulation of the nervus trigeminus is produced to a degree that effects alterations in the central nervous system through which the pain is abolished. It is at this result that the practitioner aims, whether he employs the usual chemical nerve stimulants (by injection of alcohol and other substances), or electrical (by application of Faradic currents), or thermal (by use of galvanic cautery), or, lastly, mechanical (by neurectomy, etc.). And by adoption of all those central stimuli, by various practitioners and in the various types of cases, to the nervus quintus, results have been obtained, which are sometimes permanent, sometimes transitory.

Dr. O. Chiari called attention to the fact that not infrequently neuralgias of the first and second branches of the nervus trigeminus owed their origin to traumatic or suppurative lesion of the corresponding maxillary sinus. In such cases the neuralgia is often permanently removed by treatment of the morbid condition of the maxillary sinus of the affected side.

The Treasurers of the Middlesex Hospital Cancer Charity have received from the Worshipful Company of Salters a grant of £150 towards the maintenance of the Salters' Cancer Research Scholarship.

SCOTLAND.

EDINBURGH.

Proposed Eugenics Education Society in Edinburgh.

As a result of Major Leonard Darwin's address on eugenics to the Edinburgh Medico-Chirurgical Societies, a proposal is on foot to found a local Eugenics Society. A committee consisting of Sir Thos. Clouston, Dr. Berry Hart, Dr. J. W. Ballantyne, Prof. Cossar Ewart, Dr. Brock, and Mr. Smith, Headmaster of Merchiston Castle School, was appointed at that meeting, and they propose shortly to issue a circular on the subject to persons who are likely to be interested and to join the Society. The general feeling about the Eugenics Society seems to be that the subject is one of which very little is really known, and that therefore one of the chief functions of such a body would be to try and obtain accurate data, as well as to arouse public interest in the subject. Further than that it is unlikely to go at present.

Royal Hospital for Sick Children, Edinburgh.

The directors of the Hospital have appointed Dr. J. W. Simpson, Senior Extra Physician, to be Full Physician to the Hospital *vice* Dr. Melville Dunlop, whose period of office expires next month, and the vacancy created amongst the extra physicians has been filled by the appointment of Dr. Norman S. Carmichael. Dr. Carmichael is the second son of Dr. James Carmichael, who at one time was a Physician to the Hospital, and is the author of "A Manual of Diseases of Children."

The Late Dr. David Menzies, Edinburgh.

The patients of the late Dr. Menzies have erected a memorial to their former physician in the shape of a medallion in bronze at his grave. The medallion, which is the work of Mr. H. S. Gamley, A.R.S.A., is an admirable likeness of Dr. Menzies.

The Problem of Pensions for Asylums Officers.

In his report on the Roxburgh District Asylum for the year, Dr. Carlyle Johnstone, Medical Superintendent, deals very fully with legislation. Commenting on the two Asylums Officers Bills, introduced by Viscount Wolmer and Sir John Jardine respectively, Dr. Johnstone states that Lord Wolmer's measure retains the irritating restrictions and interference with the powers and discretion of local authorities which were the subject of adverse criticism last year. Sir John Jardine's Bill discards these contentious features and makes the following provisions:—Clause 1 raises the period of service for pension to 25 years, but enables women to retire at any age, while a minimum age of 50 is presented for men. At present pensions cannot be claimed by either sex until the age of 55. Clause 2 provides for the granting of allowances to attendants permanently incapacitated by illness clearly arising from their work. At present allowances can only be granted for incapacity due to injury. Clause 4 substitutes 5 years for 10 as the number of years on which the average salary for the purpose of computing pensions is to be calculated. Clause 6 allows service of one year in an asylum to be aggregated for superannuation instead of the present minimum of two years. The seventh clause places the parochial asylums and the district asylums on more of an equality than at present. The ninth and tenth clauses attempt to secure that every officer and servant employed permanently in an asylum shall be eligible for pension, and that all permanent employees habitually working with patients shall be in the first class—*i.e.*, on 1-50th of their average salary for each year of service, whereas in the second class the rate is 1-60th. The clauses also provide that grievances shall be settled by appeal to the General Board of Lunacy.

The Mental Deficiency (Scotland) Bill.

With regard to this measure, Dr. Johnstone speaks of Clause 67, legalising contributions of Boards towards laboratories as highly commendable. He thinks that the provision establishing State institutions for defectives of criminal, dangerous or violent propensities should be extended so as to include criminal and dangerous lunatics, as at present district asylums may be forced to receive murderers and other persons of most objectionable habits and character, to the annoyance and prejudice of respectable members of the community undergoing treatment. He criticises the constitution of the new local authorities, involving the abolition of the existing Boards of Lunacy and the transference of their powers, along with the duties relating to defectives under the new Act, to District Boards of Control, as a revolutionary proposal for which the reasons are not apparent, and which will probably not meet with the approval of the public. The enactment of these changes would appear to involve the reversal of the policy approved by two generations, the relegation of lunacy administration to the domain of the poor-law, the conversion of asylums into poor-houses, and the branding of every poor subject of mental disorder as in every respect a pauper.

GLASGOW.

Glasgow Maternity and Women's Hospital Bazaar.

The bazaar held in aid of this charity realised the sum of £17,000. The opening on the third day of the bazaar was made the occasion for announcing the gift, by an anonymous donor, of £3,000 for the purpose of clinical research in connection with the Hospital.

Glasgow Assessorships and the Proposed Inclusive Fee.

The contest in the election of two assessors for the General Council in the University Court cannot be said now to be waged around the question of an inclufee in medicine, whatever it was at first, as all the three candidates now pose as opponents of such a fee. The poll, which is by voting paper, closes on the 19th inst., the candidates being Dr. James A. Adams, the Rev. Dr. John Smith, of Partick, and Dr. John Hutchison, late Rector of the High School. The two last-named are in the position of seeking re-election.

The Insurance Act and Medical Benefit.

From a report of a sub-committee of Glasgow Burgh Insurance Committee, it appears that out of about 370,000 insured persons within the burgh, entitled to medical benefit, 320,000 have made arrangements, leaving 50,000 to be allocated. The number of practitioners on the panel is 380, with lists varying from zero and unity to a maximum of 4,365. The special sub-committee proposed that those insured persons who have failed to make choice of a doctor should be distributed equally among the practitioners on the panel whose lists do not exceed 2,000, but so that no list be increased beyond that number. When the matter came before the Sub-committee on Medical benefit, an amendment was adopted recommending that the maximum number be 1,500 instead of 2,000. At a meeting of the Insurance Committee on the 12th inst. they agreed, on the suggestion of the Chairman, Mr. R. D. McEwan, to remit the minute back to the sub-committee and to defer decision on the question.

Syphilis and Insanity.

At the annual general meeting of the Western Asylums Research Institute, on the 7th inst., Dr. Ivy Mackenzie, the Director of the Institute, submitted his fourth annual report. The first part of this dealt with what had been one of the two main lines of observation in the laboratory during the four years of its existence—the significance of syphilis as a factor in the causation of insanity and of mental deficiency. It was now an established fact, Dr. Mackenzie said, that a well-defined form of insanity, numbering among its victims a considerable proportion of the inmates of all urban asylums, was directly due to syphilis, and equally certain was it that no small proportion of mental defectives owed their deficiency to a hereditary form of the same disease. It was unfortunately the case that the asylum patients and defective children who were the victims of this disease represented a more or less hopeless by-product of the infection, so far as medical treatment was as yet concerned. There was no reason, however, to believe that this would always be the case. At all events, much might reasonably be expected from more comprehensive administrative measures which would admit of early diagnosis and treatment, when the original infection could be successfully combated and its consequences obviated. For the past two years, Dr. McKenzie said, he had been engaged in an exhaustive inquiry into the prevalence of syphilis in the city. From investigations relating to several thousand cases, it was believed that from 12 to 15 per cent. of the city population were at one time or another the victims of this disease. The measures taken to cope with it were insignificant compared with the powerful means which recent scientific advances had placed at their disposal.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE LOCALISATION OF INTRACRANIAL TUMOURS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with great interest Dr. T. Gillman Moorhead's paper on "The Localisation of Intracranial Tumours" in THE MEDICAL PRESS AND CIRCULAR of November 12th, and since Dr. Moorhead invites discussion and refers largely to my own investigations published in "The Mental Symptoms of Brain Disease" (*a*) I should be very glad if you will allow me to make a few remarks upon this important and very much neglected subject.

In my investigations I have not confined myself to brain tumours, but included cases of localised injury, hæmorrhage, and other circumscribed lesions of the brain, and I have learned from these that when the brain matter is irritated by a focal lesion, the mental symptoms will show increased manifestation, but when the brain tissue is destroyed the mental symptoms will disappear. This will account for the many cases of brain tumour (discovered at a late stage) in which no mental symptoms have been observed. Another reason why mental symptoms in cases of brain tumour are so rarely recorded is that no systematic inquiry is made into the psychical condition and character disposition of the patient. If the patient can answer ordinary questions correctly and promptly, the physician is satisfied that the patient's intellect is normal; changes of character and conduct are hardly ever inquired into. Hence the scarcity of clinical records. It is therefore all the more surprising that the few cases that are fully and accurately reported should confirm the theories advanced by me. Briefly, these are:—

Firstly, with reference to the frontal lobes, that they are the most highly developed in man as compared with all animals, and that they are essential to the manifestation of the highest powers of the intellect. Other parts of the brain may be diseased or destroyed without the understanding suffering in the least, except perhaps that the ideational activity is more or less inhibited. The larger the frontal lobes the better the emotions and passions are kept under control. When they are arrested in development or destroyed by disease self-control is diminished, and the rational man changes into a man given over entirely to the satisfaction of his lower desires. In dementia the frontal lobes suffer the most, and in idiocy and imbecility the arrested development is most marked in the anterior part of the brain. Lesions of the frontal lobes frequently give rise to a state of optimism and exaltation.

In confirmation of this theory, Dr. Gabriel Chèze, Asyle d'Armentières, France, has sent me particulars of a case of frontal tumour:—

Marie V., æt. 42 years, washerwoman, entered the asylum on the 4th September, 1909. She was brought in by the police, having walked about all night in nudity, and giving incoherent accounts of herself. On examination it was found that she had no knowledge of time and place, some difficulty of speech, no idea of simple calculation and had very defective memory. She smiled happily and had optimistic ideas. Mobility and sensibility were normal; reflexes exaggerated; pupils unequal, reacting poorly; the fundus of the eyes had not been examined. No headache; no vomiting, except just before death, five days after admission. Lying on the orbital plate of the frontal bone across the crista galli was found a tumour 9 cm. in extent, adherent to the bone and dura mater, of irregular cauliflower shape, weighing 150 grammes. Microscopical examination revealed a sarcoma. Both frontal lobes, right and left, were compressed, especially the orbital convolutions, which were partially destroyed.

Secondly, with reference to the temporal lobes, lesions of this region invariably rouse exciting emotions of anger, with or without violence; sometimes there are delusions of persecution and auditory hallucinations. It may be of interest to quote a case confirming this theory published in the *Lancet*, 7th October, 1911, by Dr. W. C. Sullivan, a case which had been reported to him by Dr. R. Cunyngham Brown, of H. M. Convict Prison, Parkhurst. The patient had murdered his wife, and while awaiting trial developed a persecutory delirium which, after a period of remission, recurred with increasing mental confusion and apathy, death occurring 17 months after the date of the crime. At the *post-mortem* examination a large tumour was found infiltrating the right temporo-sphenoidal lobe. "So far as I am aware," says Dr. Sullivan, "this is the only case on record of actual homicide in this disease." He has evidently never seen my book, in which a number of similar cases are cited.

Thirdly, with reference to the mental symptoms of the posterior part of the parietal lobes, I have also published a number of cases of tumours and other circumscribed lesions showing that simple depression up to severe melancholia happens most frequently in these cases, quite the opposite to the euphoria of the frontal lobes.

A large number of cases quoted by me are the result of head injuries, but they are not to be underestimated on that account, for the circumscribed traumatic lesion has the same significance as the experimental excitation or destruction of definite brain areas by physiologists and neurologists; in fact, clinical observation is more significant and of greater value, for the experiment is made by nature herself, and not on animals, but on man. The neurologist can produce no other but motor and sensory phenomena by his experiments. He can never produce mental results; even if he could experiment on man and excite some mental centre electrically or otherwise, he could not make his subject divulge his ideas or feelings. But because of this failure we must not conclude that the primary mental powers have no centres in the brain. They can be discovered only by clinical observation.

I am, Sir yours truly,
BERNARD HOLLANDER.

London, W., November 13th, 1913.

(*a*) Rebman, 1910.

THE ETERNAL QUESTION OF TITLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an old number of the *Lancet* I find a remarkable statement by Mr. Deasy, then Attorney-General, whose opinion was asked on the folowing query:—

"Whether the Licentiates, as such, of the King's and Queen's College are entitled to the degree and title of Doctor of Medicine, and to use the abbreviation or initial letters M.D. after their names?"

Answer.—"I think the Licentiates and Fellows, as such, of the King's and Queen's College of Physicians, as such, are entitled to the degree and title of Doctors in Medicine, and to use the letters M.D. after their names.—(Signed) R. Deasy. November 21st, 1860."

The Documents submitted to the Attorney-General were, I understand, the Charter of William and Mary, and the Act of the Irish Parliament 1 Geo. III., cap. xiv., made perpetual by the Act 30, Geo. III., cap. xiv., s. 11.

I am anxious to know why the claim has been abandoned, as the College does not now seem to claim the right to confer the degree or title of M.D.

I am, Sir, yours truly,
J. C. McWalter.

Dublin.
November 9th, 1913.

[Through the courtesy of Dr. Kirkpatrick, Registrar of the Royal College of Physicans of Ireland, we are enabled to answer Dr. McWalter's query. On the receipt of Mr. Deasy's opinion, the College altered its by-laws, so as to include in the diploma the following words: "certify that he has obtained, and is hereby entitled to the degree, title, and qualification of Doctor of Medicine and Licentiate of this College." Certain licentiates succeeded in having the degree registered by the Irish Branch Registrar of the General Medical Council, but the English Registrar declined to insert it. The Irish Registrar then altered his mind, and erased the title wherever he had inserted it. A conditional order to compel him to restore the qualification was discharged without costs on May 28th, 1861, but the Court did not decide as to the powers of the College to grant the degree. This point, however, was subsequently decided in a case brought specifically for the purpose in 1864 by the Provost and Fellows of Trinity College. In April, 1864, the Master of the Rolls gave judgment "that under the true construction of the Charter of the College of Physicians of 1692 its Licentiates had no authority to use the title of Medical Doctor unless the same were conferred upon them by one of the Universities." With this decision the question has since rested.—Ed. M.P. and C.]

CHRONIC INTESTINAL STASIS.

To the Editor of The Medical Press and Circular.

Sir,—I have read with intense interest Sir Arbuthnot Lane's lecture. I dare speak only for myself, but I should be astonished to have it proved that any great proportion of men in any position had until recent years—as Sir Arbuthnot Lane suggests—regarded the subject of "chronic intestinal stasis" with ridicule and derision. The condition has, perhaps, not been labelled with the name now applied, but it has been none the less recognised. I should be more astonished to learn that this condition had, in the hands of intelligent practitioners, been uniformly treated by drugs directed to the cure of "indigestion." There is no such disease as indigestion. Indigestion is merely a name given to groups of symptoms due to scores of different morbid conditions. The symptoms can be cured only by getting at the true cause. I cannot follow Sir Arbuthnot Lane in tracing the ætiology of chronically-loaded bowels to bad feeding in infancy, but it is a condition with which, with its common symptoms, every medical man must be familiar. It cannot be successfully dealt with by any treatment not mostly made up of regimen and hygiene; and failure is often due to the stupidity and obstinacy of patients who will not submit to medical discipline. A very large percentage of patients, not confined to the poor and ignorant, treat themselves with quack medicines. It is possible that in a percentage of cases abdominal section and "short circuiting" may be called for, but in view of the seriousness of the procedure and of the fact that the shock of such an operation may be, perhaps, followed by prolonged or permanent illness, it would seem desirable to try every other rational means before resorting to it. Like most general practitioners, I have rarely made notes of cases, but I have many in my memory. In a recent case, an intellectual gentleman, aged 68, some of the worst symptoms described by Sir Arbuthnot Lane had appeared, and, in addition, he had suffered from repeated attacks of vertigo with nausea and vomiting, followed by lasting sensations of giddiness. There seemed ample cause for the symptoms in neglect of the bowels and unwise dietary, and careful general examination failed to discover any other. This case has been restored to health. With the help of the patient it has been possible to clear out the bowels and keep them clear by simple means, including strict regulation of the quantity and character of the food, and abstention from alcohol in any form.

I am, Sir, yours truly,
An Obscure Practitioner.

November 15th.

THE ALCOHOL QUESTION.

To the Editor of The Medical Press and Circular.

Sir,—This alcohol question is a very simple one. If a quantity of the juice of the grape is put into a vat and fermentation begins, the sugar changes gradually into grape sugar and so on into vinegar. Now it is a common practice in the South to stop this fermentation at any stage, so that wines of various flavours may be obtained, and this is done by simply pouring into the vat some strong spirit, generally brandy. What happens is clearly that although alcohol is the result of fermentation, that process is arrested if the alcohol exceeds a certain amount. This is a purely chemical question. It is clearly of great importance that we should distinguish between a pure wine, in which there is no amount of alcohol beyond that produced by fermentation, and any liquid, such as brandy, whisky, or such like, which would stop fermentation, and therefore must act seriously on digestion.

I am, Sir, yours truly,
Robert Lee.

LONDON NERVE CLINIC.

To the Editor of The Medical Press and Circular.

Sir,—To avoid misunderstanding, I shall be extremely obliged if you can grant me a few lines of your valuable space to make it known that the London Nerve Clinic (School of Psychotherapy) is in no way connected with any other organisation, institute or clinic, staffed either by medical or lay workers, in which psychotherapeutic methods are carried out.

Moreover, that although offering treatment on psychological lines to patients of small means, as well as to the very poor, this clinic is entirely independent of outside financial support.

I am, Sir, yours truly,
Edwin S. Ash.

71, Baker Street, W.
November 15th, 1913.

OBITUARY.

DR. R. L. BOWLES.

We regret to announce the death of Dr. Robert Leamon Bowles, late of Folkestone and Upper Brook Street, W., which took place on the 15th inst., at Priors Mesne, Lydney, Gloucestershire, aged 79. The deceased, who was educated at St. George's Hospital, qualified as M.R.C.P.Lond in 1875, becoming M.D.St. And. in 1882. He was elected F.R.C.P.Lond. in 1882. Dr. Bowles was in practice as a physician at Folkestone for many years, as well as in London. He was Consulting Physician to the Folkestone Hospital, and Physician to St. Andrew's Convalescent Home. He was a Fellow of the Royal Society of Medicine, and was for some time President of the South Eastern branch of the British Medical Association. Dr. Bowles was the author of many papers which appeared in medical journals and other publications. He contributed the article "Stertor" to "Quain's Dictionary of Medicine," an article "On Sunburn" to the *Alpine Journal* in 1888, and "Observations upon the Mammalian Pharynx, with especial reference to the Epiglottis" to the *Journal of Anatomy and Physiology*. He also wrote on the "Schott Treatment" of certain diseases of the heart at Bad Nauheim, the influence of light on the skin, and other subjects. He had retired from practice some time before his death, and had been a magistrate for Gloucestershire since 1906. He was a member of the Athenæum Club.

DR. C. McBURNEY.

The death has occurred at Brookline, Massachusetts, of Dr. Charles McBurney, one of the leading medical men in the United States of America.

Dr. McBurney was born in 1845, and was Professor of Clinical Surgery in the College of Physicians and Surgeons, New York, Visiting Surgeon to the Roosevelt Hospital, and Consulting Surgeon to other hospitals in New York. Among his contributions to surgical literature are his essay on "The Technic of Aseptic Surgery" in "Gould and Warren's International Text-Book of Surgery" (1900), and his paper, with Dr. Alen Starr, "A Contribution to Cerebral Surgery" (*American Journal of Medical Sciences*, April, 1893). His name is familiar to his profession because of his description of "McBurney's point"—the exact position of pain on slight pressure in the earlier stages of appendicitis. This description occurs in a paper which he communicated to the New York Surgical Society on November 13th, 1889.

SPECIAL REPORTS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Resolution to be moved at the Annual Meeting of Fellows and Members.

On Thursday, November 20th, the annual meeting of Fellows and Members is to be held at the Royal College of Surgeons, when the senior Vice-President, Mr. G. H. Makins, in the absence of the President, who is in America, will take the chair and present to the meeting the report of the Council for the period from August 1st, 1912, to August 1st, 1913.

The following resolutions are to be submitted to the meeting:—

To be moved by Mr. J. Brindley James: "That this 29th annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation on the Council of the College which, as now constituted, only represents those Members who also hold the Fellowship, and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation."

To be moved by Dr. A. S. Morton: "That this meeting of Fellows and Members requests the Council to include in their next annual report a balance sheet showing fully and without reserve the assets and liabilities of the College on Midsummer, 1913."

To be moved by Dr. Josiah Oldfield: "That this annual meeting of the Royal College of Surgeons places on record that it is not satisfied with the administration of the College finances as carried out by the Council, and resolves that such steps as are within its powers to take, if any, shall be taken by this annual meeting to remedy the same, and that if it has no power, the steps be taken to secure for it the necessary authority."

To be moved by Dr. W. G. Dickinson: "That this meeting, in view of the unsatisfactory nature of the regulations governing the conduct of the annual meetings, and of the small attention given to the resolutions agreed to, calls upon the Council to summon a statutory meeting of the Corporation within the next six months, in order to consider whether the annual meetings shall be continued under present conditions."

NATHAN STRAUS AND PASTEURISED MILK (*a*)

Mrs. Nathan Straus gives us an account of the work she and her husband have been doing towards saving infant life in New York. The method is the liberal supply of pasteurised milk. She regards its efficiency as shown by the fact that in the five years from its inception the death-rate for children under five was reduced from 99.0 per thousand to 76.5.

The book gives, modestly and without ostentation, the results of twenty years' experience in modifying and pasteurising milk for infants, and whether we agree that they are as great as claimed, they constitute a magnificent tribute to a great philanthropist.

Mr. Straus has devoted his time and his money to saving infant life, and he has not been disappointed. Working quietly and thoroughly he has helped to lower the death-rate for little children wherever he has gone.

REVIEWS OF BOOKS.

SMALL-POX AND VACCINATION. (*a*)

One of the most remarkable advances made in the practice of medicine during the present century is in our knowledge of the means for the production of artificial immunity against disease, yet curiously enough that method of producing immunity which is oldest and best known, and for the efficacy of which there is a greater mass of evidence than for any other, is now being more fiercely attacked than ever since its first introduction. When preventive inoculation for small-pox, or vaccination, stood alone in the field of therapeutics, with merely empirical evidence for its support, we cannot wonder that it was attacked, and attacked bitterly. Now, however, not only has the evidence in support of the preventive value of vaccination increased enormously, but the procedure itself has been brought into line with a number of other observations and a rational explanation afforded for both them and it. Vaccination as a preventive of small-pox no longer stands alone, but is merely one example of a great therapeutic method of acknowledged utility.

There is one feature in which vaccination for small-pox differs from other therapeutic measures, and it is this feature which, we believe, has stirred up against it the active hostility of so many people. Early in the last century, when the efficacy of vaccination in preventing and modifying small-pox had been established, and while the disease still continued to exact a great death-roll, the legislature made the adoption of vaccination compulsory. Such a procedure was possible while the horrors of small-pox in an unprotected community still formed a vivid picture in the minds of the people. but as the success of the enactment led to the gradual diminution of the number of deaths from the disease, the people gradually forgot the older picture in their resentment against the trouble of the procedure which had brought about its obliteration. To the parents of the present day the horrors of small-pox are practically unknown, while the troubles of a vaccinated baby are very real. Small wonder, then, that the faddist finds ready support for a propaganda which promises removal of the present evil, and the warning of those who know the risk that is being run receives scant attention. "Sufficient unto the day is the evil thereof" is the comforting doctrine which hampers the progress of all preventive medicine.

Some blame, however, must be laid at the door of the medical profession for the progress of the anti-vaccination crusade. The faddist, as is his way, has taken the trouble to make up his brief, he has devoted much skill and ingenuity to the manipulation and distortion of facts and figures, he has so altered the perspective of the picture that it no longer represents the truth, and so skilful has he become in these arts that it is often no easy matter to detect the fraud. Too many of the medical profession, satisfied with the efficacy of the measure they advocate, have neglected to make themselves conversant with the proofs of that efficacy, and so fall an easy prey to the wiles of the faddist.

Dr. Hanna has done good service to the profession and the public by the simple and clear statement of these proofs which he makes in his book. The recorded facts are stated without heat or partisanship, and the conclusions, which are drawn from these facts, follow so obviously that even the most bigoted antagonist will find little to cavil at in the method of the author.

(*a*) "Disease in Milk: The Remedy Pasteurization." Lind Guthery Straus. New York. 1913.

(*a*) "Studies in Small-Pox and Vaccination." By William Hanna, M.D., D.P.H. 8vo. Pp. 52 and xxv. plates. Bristol: John Wright and Sons, Ltd. 1913. Price 7s. 6d.

In its barest outline the case for the preventive value of vaccination may be stated as follows:—In pre-vaccination days the case mortality of small-pox varied between 25 and 40 per cent., the incidence of the mortality being greatest among children under 10 and adults over 40 years of age. At these age periods the case mortality approached 50 per cent. During the past ten years 1,163 patients suffering from small-pox were admitted to the hospitals of the city and port of Liverpool. Of these patients 943 had been vaccinated in infancy, and 220 were unvaccinated. Among the vaccinated patients the mortality was 2.9 per cent., and among the unvaccinated 27.2 per cent. Of the 943 vaccinated patients 31 were under the age of ten years, and among these there was no death; of the 220 unvaccinated patients 81 were under ten years of age, and of these 30 died. As the patients become older, and as the length of time between the vaccination and the onset of the disease increases, the death-rate steadily rises, till in later life, though it never actually equals that among the unvaccinated, it approaches more nearly to it.

We have given the baldest outline of the case for vaccination as put forward by Dr. Hanna, and must refer our readers to his book for further details, with this proviso, that the more minutely these details are examined the more strongly does the case appear. Dr. Hanna believes that his book will be useful to medical officers of health: we believe that it is a book that should be studied by every practitioner who wishes to take his part in educating the public in the fight against disease. Armed with the information that this book contains, the practitioner will be able to meet the fallacies of the faddist, to state the facts in their true perspective, and help to knowledge those whom ignorance makes an easy prey to the anti-vaccinator. To Dr. Hanna for his work, and to his publisher for the way the book is turned out, we tender our sincere thanks.

A GERMAN-ENGLISH MEDICAL DICTIONARY. (*a*)

Medical men who wish to read German medical works and who are not too familiar with the complexities of the language, will welcome this, the second, edition, of Lang's well-known dictionary. The present volume has been most carefully edited by Dr. M. K. Meyers, and it contains 4,400 definitions in addition to the more than 45,000 published in the first edition. Among the additions will be found numerous terms descriptive of diseases, signs, phenomena, etc., named after their discoverers, real or supposed. It is stated in the preface that German medical terms spelled exactly like their English equivalents have been excluded—a very wise plan if the size of the book is to be kept within convenient limits. Nevertheless, we cannot see the need for the retention of such words as "autopsie," "keratitis, "resorcin-paste," "suction," "gymnastic"—to name only a few—whose meaning is sufficiently obvious. However, the utility of the dictionary is by no means diminished by the inclusion of a few superfluous words, and it will still continue to remain the best of its kind.

THE ROYAL ACADEMY OF MEDICINE. (*b*)

The feature of this volume of the *Transactions of the Royal Academy of Medicine* is the good work recorded by several of the junior staff of the hospitals. This is particularly noticeable in the paper on the estimation of the liver function by Dr. Nesbitt, and in those by Mr. Crawford on hedonal and ether insufflation anæsthesia, and by Mr. McConnell on the location of pus in the hand. It is evident that our ideas on the relationship of the flexor sheaths to septic infection will need to be thoroughly revised. Intestinal stasis and its connection with the numerous adhesions found in the abdominal cavity has been well discussed by Mr. Wheeler. This condition is becoming more and more recognised by all operators, and it was a pity that this paper was read so late in the session that prolonged discussion on it was impossible.

The Rotunda Hospital Reports keep up, as usual, to their high standard. We congratulate the Master on the progress he has recorded. He contributes a paper on the operative treatment of pyæmia, which is probably the most important contribution to this year's *Transactions*. The results have been most encouraging. The mortality of this serious condition should be lowered by timely interference on the lines suggested by Dr. Jellett.

A case of that rare condition—typhoid spine—is recorded in a graphic manner by Sir John Moore. Mr. Hayes has an instructive paper on the X-ray diagnosis of abnormalities of the intestinal tract, which is illustrated by clear skiagrams.

The Academy is to be congratulated on the standard of the communications which have been made to it during the past year.

PROVINCIAL HOSPITAL PHARMACOPŒIAS. (*a*)

This is a most useful publication. The formulæ are given in condensed form, so that several thousands are included. It serves a double purpose. In the first place it gives the prescriber an idea of what combinations he may select in any given case; and in the second place it teaches him how various remedies may be combined to the best advantage. No medical man who actually writes prescriptions can fail to benefit by referring to this book from time to time; while for those who are unable to write a correct prescription it will prove simply invaluable. The book is produced in a handy pocket size, with somewhat sombre black boards. Might we suggest that future editions should be bound in flexible brown leather? We can strongly recommend this collection of medical formulæ which, in the majority of cases, are models of perfection.

A MANUAL OF VENEREAL DISEASES. (*b*)

The appearance of a second edition of this manual emphasises the great advances that have taken place since the publication of the first edition a few years since. The book is of special value because it represents the experience of the Army medical department in the treatment of maladies which they are able to keep under observation with more completeness than is possible in ordinary civilian practice. The first edition, it may be recalled, was the work of Colonel C. H. Melville, Colonel Sir William Leishman, and Major Pollock. The second edition has been revised and largely rewritten by Major L. W. Harrison. The serum diagnosis of syphilis is fully discussed, and it is observed that "a diagnosis of syphilis should be based on an absolutely reliable test." Noguchi's luetin reaction is also well described. As regards treatment, it is said that, properly carried out, mercurial inunction is one of the best ways of curing syphilis. The intramuscular injection of mercurial cream is essentially a military method and gives excellent results. The "cream" is made of either soluble salt, the perchloride, or preferably of insoluble metallic mercury. An all-glass syringe, with a platino-iridium needle of a rather large bore is recommended as the most suitable for the purpose—a point that will relieve those who have regarded a leather piston as indispensable. The needle is sterilised with hot olive oil. Curiously, we fail to find any mention of the familiar term "grey oil." In acute gonorrhœa vaccine treatment was found in a series of cases not to shorten the course of the malady, but the urethral secretions were found free from gonococci in the cases treated with vaccine. It appears also that vaccine lessens the incidence of epididymitis, in the cases

---

(*b*) "Transactions of the Royal Academy of Medicine in Ireland." Edited by J. Alfred Scott. Vol. xxxi. Pp. xl. and 498. Dublin: John Falconer. 1913.

(*a*) "Provincial Hospital Pharmacopœias." Comprising the Formulas for Medicinal Preparations used in twenty-five Hospitals and Infirmaries in Great Britain. Offices of the *Chemist and Druggist*. 1913. 2s. 6d. net.

(*b*) "A Manual of Venereal Diseases." Introduction by Sir Alfred Keogh. By Col. C. H. Melville, Col. Sir W. Leuhman, Major C. E. Pollock. Revised by Major L. W. Harrison. Second edition. London: Henry Frowder and Hodder and Stoughton. 1913. Price 10s. 6d. net.

noted to the extent of one-half. In chronic cases of gonorrhœa the greatest success was obtained by pushing the vaccine. Beyond noting a few points of interest, it is impossible in a short notice to give an adequate account of this book. Suffice it to say that it presents a compact and up-to-date account of the subject with which it deals. No one interested in the subject of venereal diseases—and what medical man does it not concern?—can afford to be without this excellent manual.

DISINFECTION AND DISINFECTANTS. (*a*)

Bacteriology owes so great a debt to the labours of our German friends that a work on disinfection by one of them commands our immediate interest. While the author's handling of his subject is by no means perfunctory, and much of the book is very well executed, some of the omissions are notable, and condensation is practised where detail is emphatically needed. In such a work it is unwise to mention the sterilisation of foodstuffs without reference to the conditions necessary to avoid failure, and when extolling the Pasteurisation of milk to ignore evidence that, given certain conditions, tubercle bacilli will survive. Actual errors are few, but bodily temperature is given as 96° F., and the tubercle bacillus is called an "obligate parasite." The translation has not been done with additions and alterations so as to include methods, preparations and apparatus used in England. With a hearty appreciation of Continental work, we think English disinfectants and disinfectors should have received more attention.

LITERARY NOTES.

"Hints for Regimental Medical Officers of the Territorial Force" (London: Foster, Groom and Co., Ltd.) is the title of a useful pocket book by Captain Grant, of the R.A.M.C. It is intended to supplement the knowledge gained during the initial course at a Territorial Force School of Instruction. For this purpose it is admirably adapted, while for rapid and convenient reference it will be simply invaluable, as it can be carried easily in the waistcoat pocket.

* * *

The appearance of the thirteenth edition of Pye's "Elementary Bandaging and Surgical Dressing" (Bristol: John Wright and Sons, Ltd.) reminds us of our student days, when we used to carry this little book constantly in our pocket for reference. It has served many generations of students and practitioners, and in its revised and improved form, under the able editorship of Messrs. Clayton-Greene and Zachary Cope, it is destined to hold the field in spite of its numerous competitors.

* * *

We have received the October number of Lewis's "Quarterly List of New Books and New Editions" which have been added to his medical and scientific circulating library during the months of July, August and September. These are not, of course, the busiest months for medical publishers, and consequently the list does not contain quite so many important works as usual, but as short notices are given to the best-known authors and subjects, the list forms a useful guide to the scientific publications for the period covered.

* * *

Mr. H. K. Lewis has just published a small book entitled "Lectures on Tuberculosis to Nurses," by Dr. Olliver Bruce, the joint Tuberculosis Officer for the County of Essex. It is a print of lectures delivered by the author to the Queen Victoria Jubilee Nurses. The book gives an excellent account of its subject, but we question greatly the advisability of describing the method of estimating the opsonic index and other matters of purely professional interest. In these days we fear nurses are being taught much which belongs rightly to the medical man alone. However, having said so much, we are bound to admit that this little work is in other respects excellent, and contains much valuable and up-to-date information.

* * *

The ebb tide of literature is usually emphasised by the flowing in of annuals, and the present is no exception. Already we have announced "Who's Who in Medicine" for 1914, and now we have received "The 'Wellcome' Photographic Exposure Record and Diary, 1914." Many of our readers are to our knowledge experts in photography, and to such this annual is, of course well known and appreciated. To others it may be commended because it condenses into one small volume clear, definite, and precise instructions on a very wide range of subjects. All the little wrinkles and dodges which long experience has taught the successful worker are here analysed and set forth in simple formulæ and exact directions such as help the beginner and serve as a useful reminder to the expert. Development, toning, fixing, printing, the various processes of production in warm tones and colours, and the methods of dealing with errors of *technique* are explained, particular attention being directed in the 1914 edition to green and blue toning and the production of various colours by development and other methods. On the subject of exposure this book is the last word, containing in addition to its light tables for each month and factors for plates and films, the special device attached to the cover which tells the correct exposure at one turn of the disc.

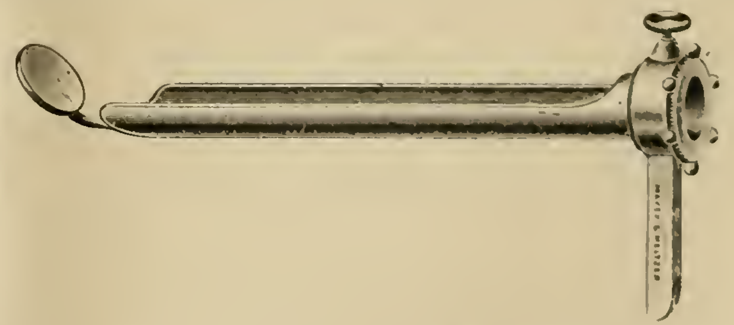
Three editions of the "Wellcome" Photographic Exposure Record and Diary are published (at the modest price of 1s), one for the Northern Hemisphere, one for the Southern, and the third, a special edition, for the United States of America, obtainable of all photographic dealers and booksellers and at all railway stations.

NEW INVENTIONS.

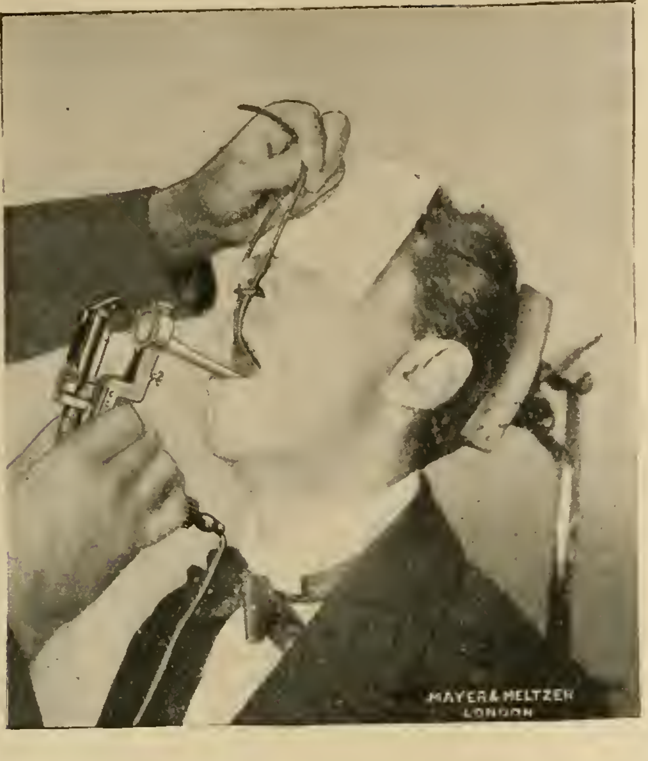
NOTE ON A NEW POSTERIOR RHINOSCOPE.

By WILLIAM LLOYD, F.R.C.S.

This instrument consists of a tubular spatula, at the end of which is a mirror which can be bent to any angle necessary for examination. The spatula is intended for use with a Bruning's handle, which it is made to fit. It is used as follows:—The ends of a piece of rubber or tubing of small diameter about 18 inches in length are passed one through each nostril and brought out through the mouth. They are then passed through the loop, as shown in the figure. The soft palate is thereby drawn forward (in the same manner as the tongue is in examination of the larynx), and so held in position. This gives ample room for the introduction of the rhinoscope. Sufficient anæsthesia is produced by spraying the floor of the nose with a 3 per cent. solution of cocaine, and the application of a 5 to 10 per cent. solution to the soft palate. If a general anæsthetic is used, it is advisable to inject a ¼ gr. of morphia an hour before the operation. The examination of the post-nasal area is considerably simplified by the use of this instrument. It gives an excellent view of the parts so that the passing of instruments into the Eustachian tubes, operations on the sphenoidal sinus, and in fact almost any operation in the post-nasal area is no longer in the nature of a step in the dark if this method is applied.



(*a*) "Disinfection and Disinfetcants." By M. Christian, Physician in Chief, Royal Institute for Infectious Diseases, Berlin. Translated from the German by Charles Salter. Pp. 107, with 18 illustrations. Crown 8vo. London: Scott, Greenwood and Son. 1913. Price 5s. net.



It will in many cases obviate the necessity for splitting the soft palate in operations on this area. I am indebted to Messrs. Mayer and Meltzer, of 71 Great Portland Street, London, for their assistance in carrying out my idea.

MEDICAL NEWS IN BRIEF.

Rotunda Hospital.

A STATED general charter meeting of the Board of Governors of the Rotunda Hospital was held on Friday. The Very Rev. the Dean of St. Patrick's presided, and there were also present—Mr. R. H. A. McComas, Mr. Henry Dudgeon, Sir William J. Goulding, Bart., D.L., Sir William Watson, D.L., Dr. E. Hastings Tweedy, Mr. R. Grant Pilkington, Sir Stewart Woodhouse, M.D., Dr. R. Dancer Purefoy, and Dr. Henry Jellett, Master.

The Primate, Sir Algernon Coote, Bart, H.M.L., and Mr. Richard Reeves wrote regretting their inability to be present.

The minutes of the last Board meeting, and of a meeting of the House Committee were read. The bank book was submitted showing an overdraft of £2,305 16s. 10d. Accounts for October amounting to £298 19s. 11d. were presented, and cheques drawn in discharge of them. The corporate seal was affixed to deeds transferring £1,630 Railway Stocks, sold to reduce the debt to the Bank of Ireland. Sundry recommendations sent up by the House Committee were considered and passed.

The Master presented to the Board, in the name of Dr. T. Percy C. Kirkpatrick and himself, the Book of the Rotunda Hospital, when it was proposed by Sir William Watson, seconded by Sir William Goulding, and resolved, "That the best thanks of the Governors be given to Dr. Kirkpatrick and Dr. Jellett for the very able, interesting and useful history which they have written of the Hospital."

It was proposed by Dr. Tweedy, seconded by Dr. Purefoy, and resolved, "That Dr. Percy Kirkpatrick be proposed to fill the office of Governor in recognition of his eminent service to the Hospital in preparing the Book of the Rotunda Hospital."

The book forms the first comprehensive history, of a large size, which has been written of the world-known Rotunda Hospital. It deals with its subject from a very broad standpoint, and will be appreciated not merely by medical men, but by every reader who is interested in the history of Dublin during the Georgian period and afterwards. Consequently it will appeal to a very large circle of readers. The profits of the sale of the book will be given to the funds of the Hospital. Pursuant to the terms of the Charter, the Board proceeded with the election of officers, when all the existing officers were unanimously re-elected for another year. After the transaction of routine business the Board adjourned.

A New Disease in the Sudan.

DR. H. B. FANTHAM, in the course of a lecture delivered last week before the Liverpool School of Tropical Medicine, dealt with the diseases of the Anglo-Egyptian Sudan. He described his pioneer researches, in company with Dr. Chalmers and Capt. O'Farrell, of the Wellcome Laboratory, Khartum, on a form of bronchitis due to a new spirochæte occurring in the respiratory passages of man. This spirochæte has not before been recorded from Africa, and very little is known about it. Both natives and Europeans suffer from bronchial spirochætosis, especially after the rains. Relapses are common, but the disease is amenable to treatment. It is widespread, endemic centres having already been found at Khartum, Omdurman, Kodok, and other places.

Associations of Non-Panel Doctors.

A CONFERENCE of Non-panel Medical Associations will be held at the Waldorf Hotel, Aldwych, on Saturday, November 29th, with the object of promoting a Federation of Non-Panel Associations. The conference is being convened by the National Medical Union, with the assistance of several leading London societies.

London School of Medicine for Women.

WE are asked to announce that the annual dinner of the Royal Free Hospital and School of Medicine for Women will be held at the Trocadero Restaurant, Piccadilly Circus, on Wednesday, December 10th, at 6.45 p.m. for 7.15 p.m. Price of tickets, 7s. 6d. J. Walter Carr, Esq., M.D., F.R.C.P., will take the chair. Applications for dinner tickets should be sent to either of the Hon. Secretaries not later than Saturday, November 29th—Dr. Winifred Cullish, D.Sc., 8 Hunter Street, Brunswick Square, or to Dr. Frederick Langmead, M.D., F.R.C.P., 47 Queen Anne Street.

The Institute of Hygiene.

A DINNER was held at the Institute of Hygiene, Devonshire Street, W., last week, to celebrate the tenth anniversary of the inauguration of the institute. Sir William Bennett occupied the chair, and amongst those present were Sir James Mackenzie Davidson, Sir Ronald Ross, Dr. Arthur Newsholme, Principal Smith, Sir Thomas Oliver, Mr. Grant Ramsay, and Dr. Murray Leslie.

The Mary Kingsley Medal.

THE Mary Kingsley Medal of the Liverpool School of Tropical Medicine was presented last week to Mr. F. V. Theobald, M.A.Camb., F.E.S.

Mr. F. C. Danson, Chairman of the School, read a letter from Sir Ronald Ross, who said that few people had played such a leading part as Mr. Theobald in the more modern development of tropical medicine and sanitation. He had made a complete study of mosquitos, on which he had written a work in five volumes which was a masterpiece.

Mr. Theobald is on Officer of the Imperial Order of the Osmanieh, Vice-Principal and Zoologist of the South-Eastern Agricultural College, Wye, and a foreign member of the Association of Economic Entomologists, Washington.

National University of Ireland.

AT the annual meeting of Convocation of the National University of Ireland the following resolutions were passed:—

"That the members of Convocation of the National University of Ireland request the Senate to create a special degree or diploma in Ophthalmology."

"That we, the members of Convocation of the National University of Ireland, request the Senate to institute lectures to be delivered to qualified medical practitioners in order to train them to become Medical Inspectors of Schools, and we further request the Senate to create a special degree, diploma, or certificate, to be conferred on those who pass a special examination."

Calls to the Bar.

The following members of the medical profession were called to the Bar on November 17th:—

Lincoln's Inn.—A. B. Dunne, Queen's Coll., Camb., M.B., B.C.

Inner Temple.—L. F. Hemmans, M.B., B.S., Durham.

Middle Temple.—H. T. Treeves, M.R.C.S., L.R.C.P., and H. W. G. Macleod, B.Sc., M.R.C.S.

Gray's Inn.—W. Moir, M.D. C.M., Aberdeen Univ., B.Sc. Victoria Univ., Manchester; G. E. Oates, M.D., B.S.Lond., M.R.C.P.Lond., D.P.H.Camb.; G. Sowden, M.D.Brussels, M.R.C.S., L.R.C.P.Lond, D.P.H. Camb.; and D. C. Kirkhope, M.D., C.M.Glasg., D.P.H.Camb.

The Royal College of Surgeons of England.

At the Primary Fellowship Examination for the Fellowship of the Royal College of Surgeons of England in Anatomy and Physiology, held on November 5th, 6th, 11th, 12th, 13th, and 14th, for which 129 candidates presented themselves, of whom 44 were approved and 85, or 66 per cent., were rejected, the following candidates were approved, namely:—

R. G. Bannerman, M.A.Edin., S. G. Billington, M.B., B.S.Lond., T. J. Cobbe, M.B., B.Ch., B.A.O., R.U.I., H. E. C. Collins, R. M. de Mowbray, M.R.C.S., L.R.C.P., I. F. Diay, E. H. Eastwood, G. W. Marshall Findlay, A. G. T. Fisher, M.B., Ch.B., M.R.C.S., L.R.C.P., J. A. C. Forsyth, M.Sc., M.B., Ch.B., H. H. M. Gould, B.A.Camb., H. E. Griffiths, R. M. Handfield-Jones, W. L. Holyoak, M.D., B.S.Lond., H. T. Hunter, M.B., B.S.Dur., L. G. Jacob, B.A.Camb., M. K. Joshi, M.R.C.S., L.R.C.P., T. Julian, M.B., Ch.B.New Zealand, O. R. M. Kelly, M.B., B.S.Lond., R. Kennon, M.B., Ch.B.L'pool, M.R.C.S., L.R.C.P., W. A. Lincoln, M.D., C.M.McGill, E. A. Lindsay, M.R.C.S., L.R.C.P., D. Loughlin, M.B., B.S., M.R.C.S., L.R.C.P., P. G. McEvedy, A. D. Marston, L.D.S., J. C. Metcalfe, M.B., Ch.B.Leeds, E. T. C. Milligan, M.D., B.S.Melb., H. W. L. Molesworth, G. T. Mullally, M.B., B.S.Lond., M.R.C.S., L.R.C.P., E. F. Murray, M.D, B.Ch.St. And., G. E. Neligan, M.A., M.B., B.Ch.Oxon, M.R.C.S., L.R.C.P., J. M. O'Donovan, R. F. O'Sullivan, M.B., B.S., M.R.C.S., L.R.C.P., J. H. Pendered, B.A., M.B., B.C., M.R.C.S., L.R.C.P.Camb., G. Perkins, J. H. Rawlinson, M.B., Ch.B.L'pool, W. H. C. Romanis, B.A.Cantab., A. Shafeek, M.D.Cairo, M.R.C.S., L.R.C.P., J. C. Storey, M.B., Ch.M.Syd., A. Sunderland, D. G. C. Tasker, B.Sc, R. A. R. Wallace, M.B., Ch.M.Syd., J. R. M. Whigham, M.B., B.S., M.R.C.S., L.R.C.P., and M. H. Whiting, M.B., B.C.Camb.

The following candidates have been admitted members of the College:—

C. S. Archer, W. S. Armitage, C. S. Atkin, B.A. Camb., F. G. Bell, F. V. B. Bevan, W. G. Bigger, B.A.Camb., G. A. Bird, J. Bostock, G. J. Bowen, H. J. Bower, E. J. Bradley, E. H. P. Brunton, B.A. Camb., N. St. J. G D. Buxton, J. Byrne, E. W. Carrington, B.A.Oxford, F S. Charnock, F. B. Chenoy, F. Cook, G. M. Coope, E. Coplans, C. H. Crawshaw, W. L. G. Davies, H. V. Deakin, H. S. de Boer, H. R. Dive, A. R. C. Doorly, E. J. Eacrett, A. T. Edwards, B.A.Camb., H. el Arculli, A. S. Erulkar, A. R. Esler, W. S. Evans, J. M. Evatt, B.A.Camb., B. J. L. Fayle, B.A.Camb., M. Ffoulkes, A. C. Hancock, R. J. Harley-Mason, F. T. Hill, T. A. Hindmarsh, E. W. N. Hobhouse, B.A.Oxford, O. R. Horwood, H. F. Hutchinson, T. H. James, G. B. Jameson, F. E. Johnson, R. B. Johnson, C. Kingston, J. I. F. Knight, N. C. Lake, J. F. Lauder, J. L. D. Lewis, C. C. Ling, W. H. Lister, G. H. Loughborough, O. G. Maginness, D. Mallam, G. N. Martin, E. E. Mather, B.A.Oxford, H. Mather, J. Millard, G. H. Monrad-Krohn, J. Y. Moore, W. Morris, J. T. Morrison, M. B. O'Sullivan, H. B. Owens, H. W. Parnis, W. P. Penhale, V. C. Pennell, J. A. Perera, A. S. Plant, J. Precopoulos, E. Rayner, B.A., M.B. Camb., S. Jessie Scott Reid, Evelyn Ritson, C. S. L. Roberts, W. E. R. Saunders, A. E. Schokman, L. E. S. Sharp, G. D. Sherwood, B.A.Camb., A. C. S. Smith, A. J. E. Smith, H. J. D. Smythe, A. K. Soutar, B.A.Camb., T. S. Stafford, W. A. Stewart, J. W. Stretton, B.A.Camb., W. V. T. Styles, L.D.S.Eng., W. E. Tanner, J. W. Thomas, J. A. Tsoi-A-Sue, F. C. Turnbull, C. B. Vakil, W. H. von Wyss, J. G. Wardrop, C. W. Wheeler-Bennett, B.A. Oxford, C. E. Williams, L.D.S.Eng., H. A. Williams, B.A.Camb., F. E. S. Willis, C. W. Wilson, H. G. Wiltshire, B.A.Camb., and H. G. Winter.

University of Oxford.

The following degrees have been conferred:—D.M.—H. G. Butterfield, Wadham; A. F. S. Sladden, Jesus; and L. T. Burra, University.

Royal Sanitary Institute.

The following new members have been elected:—Herbert S. Baker, M.R.C.S., L.R.C.P.Lond., William A. Berry, M.B.Lond., D.P.D.Oxon., Girish C. Chatterjie, L.M.S.Punjab, James A. Giles, M.B., B.S., D.P.H., Farquhar Macrae, M.B., Ch.B., M.D., James Orr, L.R.C.P., L.R.C.S.Ed., D.P.H., William G. Savage, M.D., M.B., M.R.C.S., L.R.C.P.

Trinity College, Dublin.

The following candidates have passed the final medical examination, Part I., Michaelmas Term, 1913:

Isaac W. Corkey, James N. Armstrong, passed on high marks; Amos G. Varian, Richard O'Kelly, Bertrand C. O. Sheridan, Geraldine Murphy, Francis A. L'Estrange, Thomas W. G. Johnson, Clara B. M. Adderley, Hilda M. B. Marsh, William McE. Snodgrass.

Jurisprudence and Materia Medica.—Cecil G. Sherowitz, Albert W. D. Magee.

Pathology.—Robert L. Vance.

Diploma in Public Health, Part I.—George H. Culverwell, M.B., Jas. A. Haran, M.D., C.M.G., Jane F. Colquhoun, M.B., Matthew McKnight, M.D., George F. C. Healy, M.D. Part II.— James A. Haran, M.D., C.M.G., Reginald H. Lee, M.B., Capt. I.M.S.

Final Medical Examination, Part II.—Medicine.—Eleanor E. Taylor, William F. Gibson, Frederick G. Flood, Ernest Banery-White, J. T. McCullagh, William de M. Peyton, John D. Oliver, Blacker C. Powell, Rupert C. Lowe, James C. McWalter, William S. Boyd, Herbert E. Murray.

NOTICES TO CORRESPONDENTS, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "**Reader**," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

IMPORTANT WARNING TO THE PROFESSION.

MESSRS. J. AND A. CHURCHILL inform us that there is a warrant out for the arrest of a man who professes to be travelling books for them, but who has never been employed by the firm. He calls on practitioners with samples of their books and seeks to obtain orders and payments. Among other names he uses those of Williams and Longford. They ask that he should be detained while the police are communicated with.

NON-PANEL MEDICAL SOCIETIES.

WE are asked to notify that the conference of non-panel medical associations, referred to in our last issue, will be held in London at the Waldorf Hotel, on November 29th, at 3.0 p.m. The National Medical Union, with the assistance of several leading London societies, is responsible for convening this meeting. Invitations are being issued to all known non-panel bodies, and the chief object of the conference is the promotion of the federation of non-panel organisations throughout the country.

R. P. S. (Hants).—Excision of the spleen does not, as a rule, cause any greater disturbance of bodily function than would the removal of a large cluster of lymphatic glands from the neck, axilla, or groin. After splenectomy the patient may experience pains in the long bones, and he may have some pyrexia. There is often a considerable degree of leucocytosis. These untoward symptoms gradually subside.

FLETCHERISM.

A CORRESPONDENT asks "What is Fletcherism?" As far as we understand the cult it is Americanism, and might not inaptly be described as "chewing the cud" by human beings as an aid to digestion. It implies that one should continue chewing indefinitely, so long as there is anything in the mouth, and that it should not be swallowed until every atom of flavour has vanished from the particles within reach of the teeth.

M.B.CANTAB. (London, W.).—Our correspondent might try injections of fibrolysin in his case of painful contraction of the finger. It is needless to say that the strictest aseptic precautions must be observed. One ampoule, or 2.3 c.c. may be injected three times a week in the neighbourhood of the scar.

A MEMBER OF THE INSTITUTE.

IN reply to your query, the latest weekly report of the Registrar-General showed that the births were about double the number of deaths, and that in each case the rate was considerably lower than the average.

L. T. (Gloucester) would find the solid, concentrated culture media, in powder form, known as "Solmedia," very useful for preparing quickly and readily any tube of sterile medium that may be required to grow a particular organism. The media are not expensive and have been found quite satisfactory. Messrs. Baird and Tatlock, London, E.C., are the sole agents.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 19TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE) (1 Wimpole Street, W.).—5 p.m.: Dr. Charles Singer: St. Hildegarde. Dr. John Rolleston: Medical Aspects of the Greek Anthology (Part I.). Dr. Raymond Crawfurd will show a collection of "Touch Pieces." Dr. F. W. Cook will show some Old Surgical Instruments.

ROYAL METEOROGICAL SOCIETY (Institution of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m.: Papers: Mr. W. H. Dines: The Daily Temperature Range at Great Heights. Mr. H. Harries: Eddy Wind of Gibraltar.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Communications: Mr. F. W. Chapman: Notes on the Shell Structure in the Genus Lingula—Recent and Fossil. Mr. J. C. Kershaw: Development of the Embiid.

THURSDAY, NOVEMBER 20TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Sir Malcolm Morris, Dr. Dore, Dr. Pringle, Dr. Adamson, Dr. Walsh, Dr. Dudley Corbett, Dr. Haldin Davis, and Dr. Pernet.

FRIDAY, NOVEMBER 21ST.

ROYAL SOCIETY OF MEDICINE (SECTION OF OTOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Dr. W. H. Kelson, Mr. F. Muecke, Mr. G. J. Jenkins, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS) (1 Wimpole Street, W.).—8.30 p.m.: Discussion on the Technique and Standardization of Bismuth Meals. Opened by Dr. Reginald Morton.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Paper: Dr. M. Watson: The Prevention of Malaria in Rural Districts (with epidiascope demonstration). Demonstration: Dr. H. Bayon: Lupoid Leprosy and the Results of Treatment of Leprosy by means of a Cultural Extract.

SATURDAY, NOVEMBER 22ND.

PLYMOUTH MEDICAL SOCIETY (Athenæum Chambers, Athenæum Lane, Plymouth).—8.30 p.m.: Discussion on the Treatment of Suppurating Appendicitis (opened by Dr. H. W. Webber).

MONDAY, NOVEMBER 24TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Clinical Evening.

ROYAL SOCIETY OF MEDICINE (SECTION OF ODONTOLOGY).—8 p.m.: Mr. F. St. J. Steadman: Case of Rheumatoid Arthritis Cured by the Removal of Septic Teeth. Dr. T. J. Horder: Dental Sepsis from the Point of View of the Physician.

TUESDAY, NOVEMBER 25TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF MEDICINE).—5.30 p.m.: Dr. A. M. Gossage and Dr. Braxton-Hicks: Two Cases of Non-Cancerous Tumour of the Stomach. Dr. Newton Pitt: A Calcareous Deposit on a Fish Bone in the Parotid Duct. Dr. Batty Shaw and Mr. R. Higham Cooper: Osteomalacia occurring in a Case of Atrophy of the Testicles. Dr. Percy Kidd: Case of Combined Sclerosis of the Spinal Cord with (?) Dystrophia Adiposo-genitalis. (The case will be shown at 5 p.m., previous to the meeting.)

Appointments.

CARLING, E. ROCK, M.B., B.S.Lond., F.R.C.S.Eng., Demonstrator of Surgical Anatomy at Westminster Hospital Medical School.

D'ALTON, J., Certifying Surgeon under the Factory and Workshop Acts for the Banagher District of King's County.

EVANS, ARTHUR, M.S., M.D.Lond., F.R.C.S.Eng., Teacher of Operative Surgery and Demonstrator of Surgical Pathology at Westminster Hospital Medical School.

FISHER, E. G., M.R.C.S., L.R.C.P.Lond., Medical Registrar and Tutor to the Royal Infirmary, University of Liverpool.

HALL, J., M.B., B.Ch.R.U.I., House Surgeon at the Royal Victoria Hospital, Belfast.

MOXON, FRANK, M.B., B.S.Durh., Honorary Ophthalmic Surgeon to the St. Marylebone General Dispensary.

NIX, R. E., M.B., B.C.Cantab., Certifying Surgeon under the Factory and Workshop Acts for the Chatteris District of the county of Cambridge.

ORR, VIVIAN B., M.B., B.S.Melb., Lecturer on Anæsthetics at Westminster Hospital Medical School.

Vacancies.

Certifying Factory Surgeon.—The Chief Inspector of Factories announces the following vacant appointment:—Clackmannan (Clackmannan).

Down County Council.—Assistant Tuberculosis Medical Officer. Salary at the rate of £350 per annum. Applications to R. MacIlwaine, Secretary. (See advt.)

Cheltenham General Hospital.—House Physician. Salary £100 per annum, with board, lodging, and washing. Applications at the Hospital, W. H. Head, Secretary.

Victoria Hospital for Children, Tite Street, Chelsea, S.W.—Senior Resident Medical Officer. Salary £120 per annum, with board, residence, and washing. Applications to the Secretary.

Derbyshire Royal Infirmary.—House Surgeon. Salary £100 per annum, with apartments, board, etc. Applications to the Weekly Board.

Stirling Royal Infirmary.—Resident House Surgeon. Salary £100 per annum, with board. Applications to James Dobbie, Solicitor, Stirling.

Argyle and Bute Asylum, Lochgilphead.—Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, and laundry. Applications to the Medical Superintendent.

Parish of St. Giles, Camberwell (Infirmary).—Assistant Medical Officer. Salary £180 per annum, with apartments, board, and washing. Applications to Medical Superintendent of the Infirmary, Brunswick Square, Camberwell.

Births.

BARKLEY.—On November 14th, at Athbeagh, Sandy Lane, Cheam, Surrey, to Dr. and Mrs. James Barkley—a daughter.

JOHNSTON.—On November 13th, at The School House, Highgate, N., to Dr. and Mrs. J. A. H. Johnston—a son.

LINDSEY.—On November 6th, at "Beaumont," Irving Road, West Southbourne, Bournemouth, the wife of Mark Lindsey, M.R.C.S., L.R.C.P., of a son.

Marriages.

DUCKWORTH—LEMAN.—On November 12th, at Christ Church, Lancaster Gate, Edward Dyce Duckworth, I.C.S., eldest son of Sir Dyce Duckworth, Bt., M.D., of 28 Grosvenor Place, S.W., to Cecil Gertrude, youngest daughter of Robert E. Leman, of 22 Westbourne Terrace, W.

ELLISON—LAMBERT.—On November 15th, at St. John's Church, Ealing, Dr. John Ellison, of Cromer, to Dorothy, elder daughter of Mr. and Mrs. Arthur Bradley Lambert, Westbury, Ealing.

Deaths.

BOWLES.—On November 15th, at Priors Mesne, Lydney, Gloucestershire, Robert Leamon Bowles, M.D., F.R.C.P., late of Folkestone and Upper Brook Street, London, aged 79.

SHORTT.—On November 9th, at 6 Queen's Road, Ealing, Dr. William Rushton Shortt, M.D., M.R.C.S., L.R.C.P., fourth son of the late Rev. Edward Shortt, of Woodhorn, Northumberland, and of Mrs. Shortt, of 6 Queen's Road, Ealing.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, NOVEMBER 26, 1913. NO. 22.

NOTES AND COMMENTS.

The Mountains in Labour. It is now many months since the Superintendent of the Southwark Infirmary attributed eight deaths from enteritis in that Institution to infection conveyed by flies from a number of railway trucks kept habitually by the Camberwell Borough Council. The latter body replied to this soft impeachment by a report from its Medical Officer of Health, who proved to his own satisfaction that dust could not be blown more than a few yards from the trucks, therefore infection could not be conveyed by flies. Southwark, however, was not silenced by this scientific bombshell, and called in the aid of the Local Government Board, who sent down one of its inspectors, Dr. Fletcher, to visit the Infirmary. He decided that there was not sufficient evidence to connect the outbreak of enteritis with the Camberwell dust, but he nevertheless concluded that the use of the railway siding for such a purpose should be discontinued. Two months have elapsed since this mildly elusive and velvet-gloved decision was communicated to the Camberwell Borough Council, who have done absolutely nothing so far to remedy the nuisance. Meanwhile the advent of cold weather rids the district of flies for the time being—so that the defenceless inmates of the Southwark Infirmary are relieved of one ever present danger of infection.

The L.G.B. Mouse. The mountains of the Local Government Board, as a result of their labour, have given birth to nothing stronger than a ridiculous mouse. A South London Borough simply ignores the mild exhortations of the Board. Could one have a better instance of the futility that marks much of the administration of the L.G.B.? After two months' delay that body has requested Camberwell to take "immediate steps to abandon the use of the railway siding." Where is the efficiency that one had hoped would rejuvenate the Board with the advent of Mr. John Burns, the strong man of the Government, to whom the prompt and effective handling of emergencies belonged as a second nature? Have his volcanic energies been smothered by the sheer weight of a Government office? Is he to be staved off from dealing with a fatal outbreak of enteritis by the shuffling evasions of a Borough Council, the guilt of which stands self-confessed in the shape of truckloads of filth close to the windows of a crowded Poor Law Infirmary. But the L.G.B., let us hasten to add, has an eye also to the future, for it has signified to Camberwell its wish that "the whole question of the arrangements to be made for the disposal of refuse will receive the serious attention of the Council." May it be permitted to echo this pious wish—and to trust that the siding will be gone before the next fly season arrives.

Sir Victor and the Suffragettes. A meeting of the Liberal council of the Harborough Division was held at Leicester on Saturday last to consider the representation of the constituency in view of the differences between the executive and Sir Victor Horsley, the prospective candidate, on the subject of militant suffragism. A report had been presented by the executive stating that Sir Victor's attitude towards woman suffrage, his controversy with the Government in respect to forcible feeding, and in regard to the Act passed to meet the wishes of those who thought with him, and his participation in a movement to secure a free pardon for Mrs. Pankhurst all tended to alienate from the party electors. Sir Victor Horsley was invited to speak and controverted all the points in the roport. He denied that he had made woman suffrage the most important question in his campaign, said he had always repudiated militancy, and contended that his position had been misunderstood and misrepresented. After discussion a resolution endorsing the action of the executive and regretfully cancelling the candidature was adopted by 81 to 17. Sir Victor had stated that he would accept the decision of the council.

Medical Men and the Speed Limit. THE most practical result of the adoption of the motor car by medical men has been the economy of time effected in the routine of busy practice. Most practitioners who have "changed over" from a horse carriage to some type of mechanically propelled vehicle, provided that the same is reliable, can testify to the fact that they have saved many hours in the course of the week of valuable time that hitherto would have been consumed in travelling from house to house. The general public has been the gainer also, for the call to visit a sick person can now be responded to in one-third the time by means of the modern, ever-ready-to-start, silent-running car, as compared with that required to put in a horse and drive thither. In the interests of the sick it is desirable that medical aid should be obtained as speedily as possible; indeed, it is not too much to say that, in many cases of emergency, the matter of a few minutes may make all the difference between the life and death of the patient. Can it be wondered, therefore, if medical men sometimes exceed the speed limit in towns in their anxiety to save life and to relieve pain? And yet the plea of emergency has not always succeeded in freeing the practitioner from the necessity of paying a fine in the courts for infringing this otherwise salutary by-law. The medical men in Tours have recently petitioned the councillors of that city to allow their motors to be exempt from the funereal pace of six and a half miles an hour within the city precincts, decreed by the Mayor some time ago. Their very just demands were not acceded to on the grounds that "we do not see our way to permitting doctors, in addition to the other means which they possess, and which we cannot control, to kill their fellow-citizens by running over them." A municipal edict of this kind would hardly be taken seriously on this side of the Channel.

Alleged False Medical Certificate. As the result of a recent inquest, Dr. Alexander Girvan, of Lower Belgrave Street, London, has been brought before the Westminster magistrates. The facts were that a domestic servant died last September in a Pimlico nursing home under somewhat mysterious circumstances. A coroner's inquiry was held and it was found that the deceased died as the result of an illegal operation, and the jury returned a verdict of wilful murder against some person or persons unknown. Dr. Girvan was at once arrested on a charge of having unlawfully made a false declaration concerning the death in question. He himself sent the deceased to the nursing home, but according to the evidence of the matron of that institution, said nothing about her condition that led her to suspect the real nature of her illness. In any case a medical man signing death certificates under such circumstances is placing himself in an entirely false position.

LEADING ARTICLES.

THE BRITISH MEDICAL ASSOCIATION.

THE affairs of the British Medical Association, it will be generally admitted, are of first-rate importance to medical men throughout the British Empire. The fortunes of the profession, of which it forms the chief representative organisation, are closely involved in its success or its failure. Of late years the Association has passed through troublous times, the main facts of which are familiar to our readers and need not be here detailed. The most serious aspect of the present position is apparently to be found in the finances of the Association, the deplorable condition of which is shown conclusively in the last balance-sheet issued by the Council. A careful study of that document is calculated to disturb the confidence of any candid critic. How a body possessed of so splendid a property as the *British Medical Journal* can be habitually short of money demands full and adequate explanation. If the work of the Association cannot be carried on without adopting the devices of a spendthrift, then it is surely time to face the crisis fairly and squarely. The subscription of members was some years ago raised from one guinea to twenty-five shillings; it is now proposed to raise it to two guineas. The price of advertisements in the journal, already high, has been substantially increased. The council is now asking the Association to obtain further financial corporate powers. It asks specifically for alteration of the memorandum of the Association, so as to allow a far freer dealing with the property of the members. The most significant proposal, however, and the one that demands the most critical consideration of members is that contained in clause 7 of the proposed alterations, namely, "To borrow any moneys required for the purposes of the Association upon terms and upon such securities as may be determined." This proposal suggests some reflections as to the real responsibility for the unsuccessful finance of the Association. During recent years many communications have been sent to THE MEDICAL PRESS AND CIRCULAR from men who have occupied the highest official positions in the Association. They one and all agree that the weak point in the organisation is the fact that the management of the Association has drifted into the hands of a few men. Years ago this controlling band was nicknamed the "vital centre." The new constitution of the Association was framed with a view of decentralising control. It has proved a failure. The referendum to branches is a farce. The central executive is able to flout and defy the adverse opinion of members, as proved by its retention of office in face of the storm of indignation stirred up by the acceptance of a Government post by Mr. Smith Whitaker, its then Medical Secretary. The control of members, in a word, is less to-day than ever it was over their own affairs. Happily, the whole matter is still, so to speak, in the melting-pot, for on Wednesday, December 3rd, the proposals for the alteration of constitution will be submitted to an extraordinary general meeting of members at the Connaught Rooms, London. It may be well, before members endorse the recommendations of the Council, to demand an inquiry into the financial management of the Association, especially into that of its journal, and to insert an amendment, if that be in order, limiting the central and extending the democratic or general control of the Council. It is not so long ago that the affairs of the Association were in a flourishing condition. At the time Mr. Ward Commer was president at the Plymouth meeting we believe that there was some £84,000 standing to the credit of the Association, and that with a considerably smaller membership than that which is now threatened with bankruptcy. The government of the body during this downward process has been centralised in a few hands, and it is high time that the activities of this central clique should be curtailed by the introduction of a wholesome democratic control. The phenomenon is not a new one in medical history. Centralisation, indeed, has always been the curse of the medical profession. The absorbing nature of professional work leaves it open to a few enterprising men to shape matters so as to bring corporate control within their own hands. This evil dominating power is to be seen in our qualifying corporations, in our scientific societies, in our public appointments, in our medico-social and other organisations. In the case of the British Medical Association the time has come, in our opinion, for plain speaking and for prompt action, if the future safety of our one and only great medical organisation is to be secured. It is to be hoped that a sufficient number of members will attend the meeting of December 3rd to ensure a thorough examination of existing conditions before placing additional powers in the hands of those whose stewardship has so far resulted in admitted failure.

CURRENT TOPICS.

Colour Dangers.

The colour red has been used to signify danger from time immemorable. A warning is attached to its occurrence in such divers affairs as women and railway-signals. It colours the badges of Socialism, Ulster, and the Transport Union, the ties affected by Oscar Wilde, and the street-corner receptacles of the G.P.O. It is altogether girt about with sinistry. For many of these purposes red is as good a colour as any other, but in those cases where it is needed most its inferiority is most marked. In railways and at sea lives depend upon its prompt unerring recognition, and in particular on its easy differentiation from green. For both these purposes the chosen colours are about the worst possible. In military uniforms the scarlet tunic is said to be the second most invisible, yielding only to khaki; red paint fades quickly on exposure to the sun and requires frequent repainting; and, above all, red and green are the colours most apt to be confused. About one man in twenty-five has a deficient colour sense, and by far the most common deficiency is an impaired susceptibility for red. It seems a fine example of the principle of the cussedness of inanimate objects—which makes the buttered side hit the floor—that men made such a pitiful selection. It is probably a remnant of our bovine days, when grass was a cool and pleasant green, while blood ran hot and red. Blue and yellow would be much more suitable colours from every point of view, and it is beyond the limits of possibility that they will be adopted. We always prefer the old to the better. How many medical men use the metric system?

Leprosy in the British Empire.

To the general public it may come somewhat as a surprise to learn that there are, at the present moment, about fifty lepers living in England, yet medical men know that isolated cases of leprosy appear from time to time in this country. Now and then a case is treated at one or other of our large infirmaries, but it frequently happens that the patient has to be quietly transferred to some other institution as soon as the real nature of his malady is noised abroad. Few diseases create such a scare in a hospital as leprosy, though the danger of contagion is probably less than in the case of the average consumptive. In a lecture delivered last week at the Royal Society of Medicine, Dr. H. Bayou, Research Bacteriologist to the Union Government of South Africa, stated that only one of the lepers now resident in England had acquired the disease in the United Kingdom. While a specific and sure method of treatment has yet to be found, the experience gained at Robben Island and in South Africa shows that for all advanced nodular stages chaulmoogra oil, or preferably its refined constituent, "anti-leprol," injected intra-muscularly in doses of 3-5 c.cm. at a time, remains the best palliative treatment. Early macular cases seem to respond better to other forms of treatment, such as a cultural extract prepared from Kedrowsky's isolation of the micro-organism of leprosy on similar lines to Koch's alt-Tuberkulin. While leprosy is but slightly contagious if proper sanitary precautions are taken, and any form of treatment which can be applied with any hope of success must be made use of in the very early stages, Dr. Bayou submitted that only a universal system of segregation is able successfully and promptly to cope with the spread of the disease. The Americans in the Philippines have succeeded by an energetic and consequent segregation of all cases in reducing the new admissions by 90 per cent. In South Africa, where in some colonies, out of financial considerations, only about one-half of the leper population is segregated, the rate of admission has remained constant for the last ten years. Seeing that leprosy is so far-reaching in its social results, and the individual affected is cut off to such an extent from his fellow-beings as to render his earning of a livelihood a precarious matter it is plainly the duty of every Government to prevent its further spread from the standpoint of humanity and also that of sound policy. A systematic and persevering attempt should certainly be made to get rid of leprosy in the British Empire by the institution of settlements for the voluntary segregation of the worst cases, in all parts where the numbers are too great to be dealt with at one time, as in India; and by a system of universal segregation in properly conducted asylums in those colonies and dependencies where relatively small numbers only are to be found. The experience of other countries shows that such a course would lead to a gradual extinction of leprosy.

The Sterilisation of the Fit.

In the old days men fought for the power to do. We now seek for permission to leave undone. It is a day of the pursuit of negative rights. There is a tendency to claim as such a right, the racial power of not being. A great deal of comparative sterilisation goes on amongst us, neomalthusianism, abortion, and the like. Surgery has levelled many of the difficulties that used to be in the way of controlling procreation. A reducible vasotomy gives us an easy, revocable way of sterilising the male which has been satisfactorily tested on what Americans call the unfit. The example is so tempting to our latter-day hedonists that a demand is rising for the operation to be placed, as it were, on the open market. Such a thing we all feel to be ethically and racially unjustifiable, but if once the public comes to demand such surgery, we fear the demand will be met. America, that test-tube of fantastic theories, is arguing about the question already. We hope an answer will be supplied before the problem becomes acute on this side of the Atlantic.

The Use of Smoke Helmets.

A report from the Fire Brigade Committee of the London County Council, submitted to the general meeting thereof this week, shows that science has not been at a standstill with respect to the use of smoke-helmets by firemen. The efficacy of the present type of apparatus has been under consideration for some time, and a recent report by Dr. J. S. Haldane on an examination made by him of the apparatus now employed states that he has formed the opinion that of the two types of self-contained smoke-helmets supplied to the brigade one is not suitable for fire brigade work, while the other, although defective in certain respects, can be altered so as to be satisfactory for brigade purposes. The makers of the apparatus of the latter type have submitted a set of apparatus altered in accordance with Dr. Haldane's suggestions, and satisfactory results have been obtained from the altered apparatus. Dr. Haldane also expresses the view that no man should use a smoke-helmet in circumstances of danger unless he has been thoroughly trained in its use. The committee say that the present arrangements cannot be regarded as meeting this requirement, and they think that it is imperative that steps should be taken without delay to improve the arrangements. They propose that the self-contained helmets shall be withdrawn from the ordinary running appliances and that two motor appliances specially fitted for smoke-helmet work shall be obtained, one to be placed at the chief station of the fire brigade and the other at the Euston fire station. It is proposed that the two appliances shall be manned by specially selected men, who will devote practically their whole time to maintaining the apparatus and training and practising therewith. In addition to carrying self-contained smoke-helmets, they will be fitted with dynamos and portable searchlights, oxygen reviving apparatus, and electric fans for blowing air into places where dense smoke or poisonous gases exist. The scheme also provides for smoke-helmets of a simpler and less expensive type to be kept at 19 stations in different parts of London for use, if thought advisable, pending the arrival of the special appliance. Any scheme whereby the safety of our gallant rescuers from fire is enhanced is deserving of support by the powers that be.

Dermatographia.

THE condition of the skin in which figures and letters can be traced thereupon by stroking with a blunt pencil or the finger nail, commonly known as dermographism, or dermatographia, is familiar to all dermatologists. It is usually regarded as a sign of vaso-motor instability, hence it is pathognomonic of the urticarial state. Cases are not unknown in which a whole word or a design may be written upon the skin in wheals. The phenomenon may last for several minutes, after which it gradually fades. Minor phases of dermographism are frequently seen in children and sometimes in adults with very sensitive skins, but when exaggerated the condition is a favourite one for exhibition purposes—not only at meetings of medical societies. A case of a little French girl affected in this manner has recently been exciting considerable interest in the lay press. She is said to have combined a pronounced dermatographic tendency with manifestations that, to the uninitiated, savoured of the uncanny. The writing that appeared to be supernatural was adroitly produced upon her responsive cuticle by the rapid manipulation of a hairpin—a necessary instrument of feminine toilet that serves all manner of purposes. It sometimes happens that this fictitious form of urticaria is associated with definite hysterical stigmata, though in the present case the patient is said to be normal. Unless the mucous membranes are affected, the condition, though most interesting from a clinical point of view, is not a dangerous one.

The Intra-abdominal Pressure in Pregnancy.

THE comparatively little inconvenience caused by the gradual ascent of the pregnant uterus and the consequent upward displacement of the abdominal viscera is a good illustration of the manner in which the organs of the body adjust themselves to new surroundings. It is conceivable that, in addition to bio-chemical changes set up within the maternal organism, the mere mechanical alterations of pressure within the abdomen, acting reflexly upon the sympathetic nervous, may be responsible for the vomiting of pregnancy, if not for true toxæmia. That the increase of abdominal pressure does cause the latter condition was the contention of Mr. R. H. Paramore, F.R.C.S., in an able paper read at a recent meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine. The author carried out a series of fifty-eight observations upon twenty-four pregnant women, whose intra-abdominal pressure was recorded by means of a rubber bag introduced within the rectum and connected with a mercurial manometer, with the patient in various positions. In the case of non-pregnant women with flat abdomen lying at ease in the left lateral position the pressure was only 6 to 8 mm. Hg., whereas in the pregnant the pressure was frequently found to be twice as much and sometimes more than three times. In two cases of toxæmia of pregnancy the pressure registered 18 mm. Hg. in the first, and 22 to 37 mm. in the second. That these increased pressures are due merely to the weight of the enlarged uterus is shown by these experiments to be untenable. Mr. Paramore believes that the increased intra-abdominal pressure is due rather to the tonic contraction and actual hypertrophy of the muscles of the abdominal wall. The compression of the viscera beneath affects the blood-flow through their capillaries, so that disturbed vascular conditions may play a part in the production of some of the morbid symptoms of the pregnant state. The high pressures recorded occur usually about the middle period of gestation before any yielding of the previously stretched muscle takes place. Many of our present conceptions regarding the pathology of the pregnant state may need to be re-adjusted in the light of recent research.

The Treatment of Neurasthenia.

THE essentially modern malady known as neurasthenia is often exceedingly trying for the medical practitioner to treat. In the first place, the diagnosis of the condition requires to be most carefully established, lest there be overlooked any possible organic disease of the nervous or other system of the body. The causes which lead to the gradual appearance of the neurasthenic state are numerous, and it is only by carefully training these that the patient may be placed in the right way by the removal of the exciting factors. Of the many types of the affection commonly met with in practice, Dr. J. S. Risien Russell, speaking upon the subject before the Medical Society of London the other day, stated that it is most convenient to group them into cerebral, spinal, cerebro-spinal, and psychical. Many patients suffering from neurasthenia believe that their particular case is something quite unique, and that no one has ever had their symptoms before. Such cases often try the skill and patience of the medical man to the utmost, but if he wishes to retain the confidence of his patient and to be successful in the treatment he must be careful to conceal all impatience, and, above all, he must act as though the case were unique. If a rest-cure be chosen for a neurasthenic patient it should be seen that this mode of treatment is free from every possible distraction and is really what its name implies. In some cases the use of suggestion will be more successful, dependent, of course, upon the skill of the operator and the combination of symptoms present. Dr. Risien Russell stated that the use of spermin, either alone or in combination with other internal glandular extracts, is sometimes successful alone, especially in cases of the sexual type. The use of drugs is comparatively limited, though strychnine, bromides, iron, arsenic, lecithin, phytin, and the glycerophosphates, have their place in the treatment of neurasthenia. Finally, when a patient returns to ordinary life after undergoing a rest-cure, the change must not be too abrupt, and everything likely to produce fatigue must be carefully avoided.

The Housing Inquiry in Dublin.

The Departmental Committee appointed by Mr. Berrill to inquire into housing conditions in Dublin has been sitting to receive evidence during the past week. Up to the time of writing, most of the witnesses examined have been officials of the Dublin Corporation, who have been able to furnish facts of great importance. According to Sir Charles Cameron, Medical Officer of Health for the city, the "by-laws regarding over-crowding had not been strictly carried out," and could not be without an increase of his staff. Since 1890 the Corporation has had Parliamentary power to regulate the number of persons living in tenements. Each resident must have a minimum of 320 cubic feet of space. Up to the present no register of tenement rooms giving the cubic space in each is available, though one is in preparation. Inspectors visit the houses for over-crowding every six or eight weeks, carrying measuring tapes to estimate the cubic space. The population of these residences is, however, a floating one, and, as Sir Charles Cameron admitted, the number of residents to-day is no guide to what it may be next week. As regards sanitary accommodation, Sir Charles Cameron thinks that about one-half the tenement houses have sufficient. About 2,000 of the 5,712 tenement houses require to be re-built. We do not propose to comment on the evidence at this stage. It is abundantly clear, however, that some tribunal more independent and representative than a Committee of the Local Government Board is required to conduct an inquiry into the question. In saying this we add that we believe that Mr. O'Conor and his colleagues on the Committee are making an able and honest effort to obtain a knowledge of the facts. The Local Government Board is, however, next to the Dublin Corporation, the body responsible to public opinion for the present state of affairs.

The Health of the Indian Army.

The Blue-book recently issued regarding the health of the Army in India shows that the improvement begotten of Lord Kitchener's sanitary measures has been well maintained. It is indeed significant that the change for the better in this respect only dates from 1902, when Lord Kitchener assumed the command in that country. His hardening marching schemes, no less than his sanitary enactments, deserve credit for this. Anti-enteric inoculation has maintained its satisfactory results, even though its fallibility is once again demonstrated, for the ratio per 1,000 of hospital admissions for enteric among the inoculated (who now number 85 per cent. of the European troops) was 1.7, and the ratio of deaths 0.17. Among the non-inoculated the rates proved much higher; yet the fact that in spite of all experiments inoculation is so clearly not infallible may be regarded by some as a justifiable extenuation of the troops who still refuse to submit to the operation. Moreover, it must always be remembered that a goodly proportion of the refractory 15 per cent. are men who have either already had enteric fever or who have approached the evening of their Army career without having contracted it, and see no good reason for being inoculated just as they are about to return to civilian life. The point is, of course, that compulsory inoculation, like compulsory vaccination, tends to lessen the case-incidence of typhoid fever, as well as to render the disease far milder in its attacks. Past experience has shown the fearful ravages made by enteric fever amongst troops on active service, and any measure that minimises such a risk to the soldier should be welcomed rather than discouraged.

PERSONAL.

Dr. Colston Wintle has been re-elected Chairman of the Bristol Health Committee.

Dr. John Playfair has been elected President of the Edinburgh Medico-Chirurgical Society for the ensuing year.

Dr. H. W. Barber has been appointed Physician to the Skin Department at the Evelina Hospital for Sick Children Southwark.

Dr. F. C. Linton, Deputy Medical Officer of Health for Croydon, has been appointed Medical Officer of Health for Tunbridge Wells.

Dr. Herbert E. Cuff, M.D.Lond., F.R.C.S., has been appointed Principal Medical Officer to the Metropolitan Asylums Board.

Mr. G. Grey Turner, M.S.Durh., F.R.C.S.Eng., has been appointed Lecturer in Surgery in the University of Durham College of Medicine, Newcastle-on-Tyne.

A handsome memorial tablet to the late Mr. J. H. Targett was unveiled the other day in All Souls' Church, Langham Place, W., by Mr. Charters Symonds.

Mr. L. E. Barrington-Ward, Ch.M.Edin., F.R.C.S. Eng. and Edin., has been appointed Surgeon to Out-Patients at the Hospital for Sick Children, Great Ormond Street.

A memorial to the late Dr. R. Arthur Prichard, who on several occasions had been Mayor of Conway, in the shape of a stained glass window in the old parish church of Conway, was unveiled the other day by the Dean of Bangor.

Dr. W. S. Kerr, of Sheffield, was the recipient the other day of a suitable presentation upon the occasion of his retirement from the post of Hon. Secretary of the Sheffield Medico-Chirurgical Society, which he has held for many years.

The medical men of Swansea have signalled the retirement of Dr. Nelson Jones and Mr. Brook from the local hospital staff after 20 years' honorary service, and their appointment, under the rules, to the consulting staff, by entertaining them at a complimentary banquet.

Dr. and Mrs. J. Kennish, of Clapham, were the recipients of a handsome testimonial the other day from fifty professional colleagues in appreciation of their valuable services in relation to the Provisional Medical Committee for the Wandsworth Division of the British Medical Association during 1911-12.

CLINICAL LECTURE
ON
POST-INFLUENZAL NEUROSES AND PSYCHOSES. (*a*)

By SIR GEORGE H. SAVAGE, M.D., F.R.C.P.Lond.,

Consulting Physician for and Lecturer on Mental Diseases, Guy's Hospital, London; Consulting Physician to Earlswood Asylum.

INFLUENZA has recurred at irregular intervals, and it is reported that in 1580, after or with the epidemic, hysteria and other functional nervous disorders were noticed; more recently, in the eighteenth century, similar association was noticed, and in 1836 there was an epidemic on which Sir Henry Holland reported, noticing the occurrence of nervous symptoms. Dr. Crichton Browne recorded cases of insanity in 1874. In 1891, we had a severe recurrence of influenza in England, and for a time there was doubt as to its having any influence in the production of insanity. In fact, I was one of the first to point out that a good many of the patients who were being received into Bethlem Hospital had suffered from the disease. Then arose a rather feeble discussion as to whether there was anything like a true post-influenzal insanity; we had not got beyond the narrow view of special forms of disease following particular influences. It has taken a long time to get it understood that the nervous system has only a limited number of ways of expressing itself, and that it does this whether the organ is being destroyed or is only interfered with. It was thought that the sane suffered more than the insane, and here was a very pretty mistake. It was found that the nurses at an asylum suffered more from the epidemic than did the patients, the explanation being simple. The nurses went out and about and were exposed to contagion, whereas the patients were only very slightly exposed; anyway, this seemed to prove that the malady was contagious. It is now fully recognised that it is due to some—at present unknown—toxic agent and that it is contagious.

In considering the affections of the nervous system which are associated with the disease, we shall have first to note that in many respects they are like the disorders which are met with after other febrile disorders, but that as in most of these there are specific differences which are noteworthy. I have no doubt that the neuroses following influenza occur most commonly in those who are weakened along nervous lines, in one way or another, hereditary predisposition was very common and still more potent was the fact that the patient had had some previous nervous or mental troubles. I have no doubt, too, that alcoholics suffered more than the temperate. I could not say that in my experience mental symptoms occurred more frequently in one sex than in another; I met with neuroses at all ages. It was interesting to find that certain cases of general paralysis seemed to start with the influenza. In all these cases the disease was latent, but all were predisposed to the degeneration through syphilis or alcohol or both. In the earlier days one had not the opportunity of verifying the syphilitic connection with general paralysis of the insane which we have now, and we had to accept the history which was given though often we had our doubts about its truthfulness. My own opinion is that influenza alone without syphilis would not produce general paralysis of the insane.

In the earlier epidemics the simpler functional neuroses were recorded, but little or no notice was given as to the graver ones. I do not suppose there were no psychoses then, nor do I believe there were any very marked differences in the epidemics then and now. It is noteworthy, however, that the former ones seemed to depart altogether for a generation or more leaving no aftermath, but we have never been free from the plague since 1891, and though it has been at times less in evidence I believe it has left behind a something which has crystallised itself into the name of "influenzal" colds. The earlier noticed symptoms were functional, hysteria and hypochondriasis being more prominent; later the forms of neuralgia and neuritis were recorded.

I shall now proceed to give my own experience. First, then, I would say there is no specific form of mental disorder which deserves the name of influenzal insanity. The nervous and mental symptoms may occur with the onset of the affection during the acute or febrile stage, or may follow at a longer or shorter interval as sequelæ.

Among the more simple neuroses I have met with a host of slight symptoms, each epidemic having some peculiar character. Thus in one I met with gastric disorders; in another the throat was chiefly complained of; while in another a large number of patients were said to be suffering from neuritis. I, personally, have never had a severe attack of influenza, but I may say that I have sampled all the minor troubles. I shall never forget the neuralgia which was present in one illness. This was of the following type: Suddenly I felt a sensation of heat over one side of my face and head, this was soon replaced by agonising neuralgia which for an hour or more almost drove me to distraction, then as suddenly as the attack came on, it left completely, only to return in several hours; thus about three times in the twenty-four hours I had these neuralgic attacks. I found phenacetin the best remedy, though I thought alcohol was of some service. Another form which I have not seen described was a renal affection, the headache and eyeache being followed by most marked polyuria and with this the attack passed off. I shall not spend more time in referring to these slight neuroses beyond saying that during an influenzal epidemic many other disorders seem to be affected by it, and in treating them it is well to remember this. I think I must here refer to one of the symptoms which may occur early in the disease but which

---

(*a*) Lecture delivered at the London Post-Graduate College, November 19th, 1913.

is not often recognised till the acute stage has passed and therefore is generally looked upon as a sequela. This is loss of smell. I have met with a very large number of patients thus suffering, and I find that if recovery take place it is very slow. Deafness is common during the attack and may persist, but once I met with a patient in whom the influenza seemed to improve the hearing. I had to see an old man who was suffering from acute mental disorder, and it was important that some one should during his illness have power to conduct important business. It was decided to get a temporary order for administration of his affairs, and for this purpose I had to see and examine him. I was told he was very deaf, and this I found was true; I had to shout to get him to understand me; later with the influenza his hearing improved so much that he understood when I spoke in my ordinary tone.

I have not myself met with cases in which affection of sight of a temporary nature was associated with influenza, but I believe this has been noticed.

As I have already said, I look upon hereditary predisposition as a most important point in considering the forms of mental disorder associated with influenza. Whereas delirious states and mania of a delirious type may follow the affection in healthy patients, where there is family neurosis the tendency seems to me to be the development of the more organised forms of insanity. In these cases hallucinations of the senses, specially of hearing, occur. It is noteworthy that a previous attack of mental disorder may take the place of inherited tendency. Patients who have had previous attacks of mental disorder frequently break down again when they have influenza.

Next I have no doubt that persons who had injured their general health by alcoholic excess are more likely to have mental disorder after influenza than are the more temperate; the tendency, in my experience, in these cases, is for the disorder to assume an acute delirious type, so that I have seen a certain number of cases in which it was difficult to decide whether they were suffering from delirium tremens or delirious mania; I think probably the temperature might help in the diagnosis, but I only throw this out as a suggestion, as I have no facts to go upon.

Next I would refer to cases in which there may be some other toxic infection or cause of infection. I saw a good many cases of puerperal insanity associated with influenza, and dreaded these cases as they assumed in most instances the delirious and dangerous type.

Though I shall have later to refer specially to the connection between general paralysis of the insane and influenza, I must complete this part of my subject by saying that I have met a good many cases of general paralysis of the insane in which influenza was given as the cause of the disease, and I was able distinctly to trace the outbreak of the acute symptoms to the toxic cause of influenza associated with the specific cause.

Neurasthenia, one of the most marked after-effects of influenza, is the profound nervous exhaustion which seems to be out of all relationship to the febrile disorder which has been present. When all the acute symptoms have passed the patient who feels recovered attempts to return to his work or else goes into the country with the idea that a slight change will complete his restoration. In the latter case he is disappointed to find that a single round of golf or a fairly long walk leaves him prostrate, but without any feeling of pain. He hopes that what he looks upon as the stiffness or weakness due to want of exercise will pass, but instead of this he finds himself more and more exhausted with exercise. Similarly, the patient returning to his professional work or business starts hopefully, and for a time he is all right, only feeling the intellectual work tires him unduly. In a few cases I have met with patients whose return to work was associated with almost unnatural buoyancy and feeling of capacity; this soon passed, leaving depression and exhaustion. These cases are typically neurasthenic and require very careful and prolonged treatment. I have seen several doctors who have returned to work too early, and after several relapses have had to take rest-holidays lasting for several months; such holidays are best taken by the seaside, and I believe sea voyages are the best of all. Here, again, I believe a moderate amount of good wine is of service.

But now to return to the more special mental disorders associated with influenza. As I have already said, these may occur with the onset, and in such cases they may seem to bear some relationship to the febrile symptoms. I have seen some of the most acute cases of acute delirious mania, which have been looked upon as cases of meningitis or cerebritis, following within a few days of the onset of the influenza. These cases may have no other apparent cause, but I have described cases in which some contributing cause, such as pregnancy or parturition, has had a share in their causation. In one case acute syphilitic fever was connected with an acute attack of mania. Acute delirious mania when uncomplicated rarely has any marked rise in temperature, but in the cases associated with influenza this does not hold good. The symptoms of this disease may be briefly given. Headache, eyeache, followed with great restlessness, in which there is very active and agitated sleeplessness. The patient soon develops hallucinations of sight and hearing; food is often refused. The almost uncontrollable restlessness leads often to difficulty in keeping the patient in bed. The tongue becomes dry, and inattention to the calls of nature may follow. The temperature may be only a few degrees above normal, but with influenzal cases I have known it rise to 105° or 106°. This state may last for some weeks; it almost always requires asylum treatment. It ends fatally in at least one-third of the cases; in one-third complete recovery will probably take place; but of the other third some become mental cripples for the rest of their lives, while some are subject to recurring attacks of mental disorder. Personally, I believe in abundant feeding and the use of alcoholic stimulants.

Nearly allied to the above are the cases of acute confusional mental disorder; there is less excitement, no rise in temperature, but a general mental confusion often with visual or auditory hallucinations. These, like the last, have in my experience occurred chiefly in young persons. The confusional cases are hopeful in prognosis, though I must say that in post-influenzal cases the progress is often very slow towards health. There is a great danger of relapse, and as I have said you have to encourage with hope for long periods. In patients who are neurotic by heredity, an attack of influenza may either accentuate a tendency or establish a morbid habit. Thus I have known young men and women who have always been looked upon as shy and introspective, or who have been highly conscientious, who, after an attack of influenza, have slowly developed paranoiac symptoms. In these cases the prognosis is not good, but when the cause has been influenza I do not give up hope for long periods. A much more grave condition is that in which young people, belonging to insane families, at or about adolescence, break down with some form of emotional mental disorder. In these, hysterical outbreaks or the development of immoral tendencies may follow an attack of influenza. Such cases not infrequently turn out to be cases of dementia præcox.

The relationship between influenza and general paralysis of the insane is very interesting. First I do not believe that general paralysis of the insane ever arose from simple influenza. But I have seen examples of general paralysis of the insane which have followed directly on an attack of that disease. In some cases after the confirmation of the diagnosis of general paralysis of the insane, the friends admit that the patient had been changing slowly for some months before the mental breakdown. In some there was the very characteristic sleepiness; in others, change of habits in some small and immaterial way. An attack of influenza follows. This may be of only a very slight kind; in fact, I have met with cases in which the patient was said to have only had a slight influenzal cold, but whether the illness has been slight or severe soon after it has passed the friends notice the physical signs of general paralysis of the insane, the change of expression, the alteration in speech and gait. Though in these cases the tendency is to follow the ordinary course of decay, I have rarely come across cases in which there was much general exaltation of ideas or very marked irregularity of conduct. More generally they pass rather rapidly into dementia. I have no statistics as to the occurrence of fits or of the duration of the disease. In these cases, again, I think asylum care is the best for them and for their relations.

I have so far referred only to the disorders which follow influenza occurring in normal persons, though I have said that I have met with cases in which the recurrence depended on influenza in cases of returning mental disorder and in cases in which there have been previous symptoms of a neurotic kind. I have seen recurrence of fits in patients who have had fits before. I have seen temporary relief from migraine and from spasmodic and hay asthma following an attack of influenza, and even slight apparent mental gain in some cases of chronic insanity, but all these have been very temporary.

There is a branch of the subject which I have not hitherto written about; this is what may be called the ethical and the medico-legal sides. You all know the dread of the term "insanity," and the dislike to the word "asylum." To take the latter first I always make a point of treating acute influenzal cases out of asylums if possible, for they are so eminently curable that one wishes for the sake of the relations to avoid the stigma of "asylum." Next, I have had innumerable inquiries from patients who have had attacks of mental disorder following influenza as to whether they were really "insane." I admit the great difficulty in being quite honest, yet doing what is for the best interest of the patient. "Mental breakdown" is a very useful term, and I have found that the patient has derived comfort when she has been told that she had "meningitis." I would never withhold from the patient, on his request, as to whether he had been really out of his mind the fact that for a time in my opinion he was not himself. If you go further you will often find yourself landed in a very awkward position. The patient may resent the fact that he has ever been certified and may look upon his own doctor as having done a very wrong thing in certifying him. You know that certification of anyone in the Army practically removes him for ever from the Service, and I have seen some very hard cases in which young officers after an attack of influenza have been certified though their mental disorder has been transient and they have been removed from the Service.

Another example of the medico-legal aspect of post-influenzal neurosis is that of a young Naval lieutenant who, after an attack of influenza, lost his aptitude and being navigating officer managed to run his ship aground in a fog. He had got into a state of nervous weakness and failed to recognise the lights. He was transferred to another ship, but here again he got into a muddle when directing the course of the ship, had to be removed from the bridge, and passed into a more active state of mental disorder which passed off only after prolonged rest.

I sum up, as I did on a previous occasion, with an adaptation from the work of Dr. Leledy, of Bourges. Influenza, like other febrile disorders, may set up psychopathy. Mental disorder may follow at any stage of the influenza. Influenza in the production of disorder may be associated with other causes. It may be the predisposing or the exciting cause. In all cases there is some acquired or inherited predisposition to neurosis. The mental and nervous symptoms depend probably on true brain changes due to some toxic influence.

The nervous symptoms may be sudden and need bear no relationship to the severity of the influenza.

The curability depends on general rather than special ("influenza") condition. Dr. Leledy thought the insane less liable to the disease than others; I have my doubts about this.

In a few cases neuroses were relieved by the influenza. Thus there may be temporary remission during the acute stage of influenza. No special line of treatment can be indicated. There may be medico-legal aspects to the disorders following influenza.

The above put plainly are my own experiences.

I must not omit to notice the large number of persons who, having had attacks of influenza, never recover completely. I have described such patients as mental cripples, and I know no better term to describe them. They are changed in some way, often to so slight an extent that all that the relations can say is that they are not themselves.

I have met social and marital incompatabilities arise as a consequence, and in others I have known defective higher control so that the person no longer has a truly moral sense.

I have known persons who were good in some special art after influenza cease to be able to make a living, yet quite unable to appreciate their own defect.

Such cases I look upon as hopeless. They are too old for re-education, and have to be placed with the feeble-minded.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by J. M. Munro-Kerr, Muirhead Professor of Obstetrics and Gynæcology, Glasgow University; Gynæcological Surgeon, Royal Infirmary, Glasgow; Obstetric Physician, Glasgow Maternity and Women's Hospital; Hon. Fellow American Gynæcological Society. Subject: "Extrauterine Pregnancy."*

ORIGINAL PAPERS.

ON NEPHROPEXY.

By J. LACY FIRTH, M.D., M.S.Lond., F.R.C.S.,
Surgeon to the Bristol General Hospital.

My object in this communication is a double one—to express appreciation of the operative *technique* in nephropexy recommended by William Billington, and at the same time to emphasise the fact that in the operation great caution has to be taken to avoid wounding the pleura. I also record a case in which this accident occurred in my practice (*a*).

It was in Nov. 1910, that I decided to try the method of Billington for fixing a movable kidney. For several years previously, following Jonathan Hutchinson, jun., I had been fixing kidneys with kangaroo tendon sutures passed through the organ and through the muscular edges of the wound on each side. Earlier still I had practised the method of Edebohls, in which the renal capsule is deflected from both the anterior and posterior surfaces of the kidney halfway to the hilum, and the deflected portion of the capsule and the undeflected part near by are transfixed with fixation or suspension sutures, the ends of which are carried through the muscles on each side of the wound. My reason for changing from Edebohl's method to Hutchinson's was the feeling that it was a mistake to decapsulate the kidney, because decapsulation seemed unnecessary, and perhaps caused some atrophy of the renal cortex. It appears to me to-day that partial or even complete decapsulation of the kidney is a procedure which leads to no appreciable evil results, and that it is the one procedure which most certainly secures firm adhesion between the kidney and surrounding structures. In this connection I may allude to the experiments on cats made by Harold W. Wilson and C. M. Hinds Howell. These writers, comparing the results of suturing without decapsulation and suturing after partial decapsulation, say, "We can confidently assert that that of decapsulation secures by far the more efficient fixation."

My reason for passing to Billington's method after using the others described was that by it the kidney is fixed at a normal level, whereas in the other two the kidney is fixed at a level considerably lower than normal.

Writers have alleged that no harm results from fixing the kidney in a lower position than normal, if the fixation holds good. Others have reported troubles which seemed to be due to the low position in which the organ had been fixed. One of my patients in whom I had fixed the kidney rather low, after an interval of six months of relief, began to complain of pain in the corresponding lumbar region of the abdomen, and she continued to complain for eighteen months or more. At last, in desperation, I determined to try and refix the kidney at a higher level. I found, however, that the kidney was so firmly adherent that it was impossible to improve its position, and I had to give up the attempt. I cannot be at all certain that this patient's pain was due to the low position of the kidney. She is a person never without pain somewhere. Before her kidney had been touched she had had a more or less normal appendix removed for pain simulating appendicitis.

The above is the only example I remember seeing of trouble due, or probably due, to fixation of the kidney in too low a position. Billington after quoting with approval Goelet's statements that "fixation of the kidney lower than normal is worse than mobility," and that "this is what produces the great percentage of failures," states that he himself has several times had to operate upon kidneys previously fixed too low, and which were causing severe pain.

Anatomical considerations suggest that a fixation of the kidney in a low position may result in kinking the ureter, and cases of hydronephrosis following renal fixation have been attributed to this state of affairs.

On the other hand, some writers have recommended fixing the kidney lower than usual to avoid the exertion of pressure upon it by the liver, specially during inspiration, which pressure tends to displace the organ again, or to flex its upper pole. Fixation of the kidney to the last rib has been particularly objected to, because the normal movement of the last rib is upwards with inspiration. The kidney should move slightly downwards with inspiration to avoid diaphragmatic pressure.

My first impressions on reading Billington's description of the operation he uses were that the method was condemned by its meddlesomeness and complexity. But I have found it easy to perform, and not so complicated as its description might lead one to suppose.

For anything like a complete description of the operation here labelled Billington's I must refer the reader to that surgeon's original writings. He lays no "claim to originality in connection with any particular step in the operation." Methods and principles suggested by Edebohls, Fullerton, Goelet and Brödel have been combined in the operation, and the combination of methods adopted seems to have been first used by Jordan Lloyd.

Briefly outlined, the following are the steps of the operation: (1) Oblique incision, beginning over the eleventh intercostal space; (2) separation of the fat and perinephric fascia "from the muscles of the back for some distance above and below the last rib"; (3) dislocation of the kidney into the loin, and separation of all adhesions and fat; (4) deflection of a flap of renal capsule downwards from the upper half of the kidney, two-thirds of the flap being from the posterior surface, one-third from the anterior; (5) insertion of two supporting sub-capsular sutures, after the manner of Goelet and Brödel, into the lower half of the kidney, the ends of these being long to pass through the muscles and skin above the wound to be tied over gauze rolls; (6) passing a curved Spencer Wells forceps through the eleventh intercostal space at the edge of the erector spinæ muscle so that the ends of the forceps curve

---

(*a*) *Bristol Medico-Chirurgical Journal*, September, 1913.

round the last rib and project below into the upper part of the wound; and (7) passing the capsular flap, grasped in the forceps mentioned, over the last rib and suturing the portion drawn out down to the capsular surface of the kidney at the lower border of the rib.

Billington's assertion that, by the method of operating outlined above, the kidney can be fixed in a normal position is based upon investigations made by him in conjunction with Professor Arthur Robinson. He writes: "Dissections of formalin-hardened bodies were made. It was found, with great constancy, that in the normally-placed kidney the angle formed by the last rib and the outer edge of the erector spinæ corresponds to a point on the posterior surface of the kidney midway between the upper and lower poles, and about half-way between the hilum and convex border." This middle point of the posterior surface of the movable kidney can be brought almost exactly to the other corresponding point, that is to the angle of the last rib and erector spinæ, by the operation described. The capsular flap in the operation, as pointed out above, is detached downwards only to the level of a line midway between the upper and lower poles of the kidney. In other words, the flap remains attached to the kidney by its base-line at this level, and the base-line is brought into contact with the last rib, covered by the diaphragm, when the flap is drawn taut over the rib. The kidney need not be placed so high. If the liver has a lower position than normal, and encroaches upon the space which is ordinarily filled by the upper pole of the kidney, it will be wiser to fix the kidney in a position a little lower to avoid downward pressure.

The most serious drawback of the Billington operation, to my mind, is the danger it entails of wounding the pleura when a channel is being made over and beneath the last rib. I have performed the operation ten times. On each occasion, when taking this step in the operation, I have been afraid that I might hear that unpleasant hissing sound which is made when air enters the pleural cavity with inspiration through a wounded pleura. At the sixth operation I had the mortification of hearing that sound. I give further details and the subsequent history of the case below. Such an occurrence immediately suggests the question whether this step in the operation is worth taking or not. The uppermost suspensory Brödel suture brings the base-line of the flap and the kidney to the proper level, and retains them there for three weeks. Is not that sufficient? If not, the fixing power of the flap then comes into play, for the suspensory silk-gut sutures are removed. For the first three weeks I consider the capsular flap to be almost useless.

On the subject of the relations of the pleura to the seat of operation and the danger of wounding it Billington makes the following remarks: "Usually the pleura does not extend below the lower border of the last rib, and for one and a-half inches from the tip it terminates at or above the upper border. In some cases, however, the pleura extends lower." And again: "The only precautions necessary are to use a blunt instrument, to keep close to the rib, and to make the puncture not more than one and a-half inches behind the tip. I have executed this manœuvre upwards of 350 times, and have only opened the pleura once."

Before my sixth operation the above statements gave me considerable confidence in my ability to avoid wounding the pleura, but since the accident hope has had to replace confidence. My hope for the future is the greater because the instrument I used for clearing a space around the rib was not sufficiently blunt. I was not in possession of a curved Spencer Wells forceps, the instrument recommended by Billington, so I used an aneurysm needle. It is quite likely I should have safeguarded the pleura if I had used blunt forceps.

There are, however, facts which show that the pleura is liable to puncture in any operation for exposure of the kidney by the lumbar route if the deeper part of the incision at its upper end is carried to or nearly to the lower border of the last rib, or to the rib which is supposed to be the last one. Thus in Jacobson and Rowlands's "Operative Surgery," a case is mentioned in which the accident occurred because the last rib was rudimentary, and the pleura came down well below the eleventh rib. The moral to be drawn from that case is that the ribs should be counted from above. Also Lange is quoted as having shown that in exceptional cases the pleura may descend considerably below a normally developed last rib. I have myself seen the pleura opened in exposing the kidney apparently because the pleura descended below the last rib.

The case I report below appears to me worth recording, not only as a warning of the danger under discussion, but also because it illustrates the possible effects of the accident. It will be noticed that dyspnœa gradually increased for two days, but was not noticeable for several hours after conclusion of the operation. These facts suggest that air continued to enter the pleura for many hours. How that could happen is difficult to understand. There was a drainage tube, a small one, in the lower part of the wound, but this was some inches below the last rib, and the kidney lay vertically between the tube and pleural wound, and of course there was a large dressing over the wound.

The following are notes of the case:—

Miss L., æt. 23, had a very mobile right kidney, and suffered much from dyspeptic symptoms. A gastric ulcer had been suspected to exist. On October 31st, 1912, the kidney was exposed, brought out on to the loin and all adhesions separated. The capsule was deflected from the upper half of the kidney in the way described above. The last rib was then cleared at the border of the erector spinæ, an aneurysm needle being the instrument used for the purpose. As the needle end appeared in the upper part of the wound at the lower border of the last rib air began to enter the pleura. Mops were immediately applied to the spot to prevent further entry of air, and it was decided to cut away the capsular flap and trust entirely to the two supporting silkworm-gut sutures to retain the kidney in place. The lower half of the kidney was smeared with pure carbolic acid. As soon as the kidney was drawn up into position by the sutures all suction of air into the pleura seemed to cease. No effects from the air entry could be detected either by the anæsthetist or by me, and my impression was that very little air had entered the pleura. A small drainage tube was placed below the kidney, and the wound closed in layers. I saw the patient again six or seven hours after operation. She was in some pain, but appeared to have no respiratory trouble. At the end of twenty-four hours, on November 1st, she complained of some difficulty in breathing, and there were the physical signs of a pneumo-thorax over the front of the right chest, and the heart's apex beat was about an inch outside the nipple line on the left.

November 2nd (forty-eight hours after operation).—Difficulty in breathing more marked, respirations rapid, patient rather dusky in appearance, resonance on percussion from the right chest across the middle line to slightly beyond the left edge of the sternum in the cardiac region. The apex beat was still further displaced to the left.

An aspirator needle was therefore passed into the chest on the right side through the seventh intercostal space near the posterior axillary line, and connected with the vacuum made in a Winchester quart bottle. Air immediately passed into the bottle from the chest. At the same moment the patient began to have a series of short coughs, rapidly repeated, and she became more dusky and distressed. The vacuum was shut off, and after a pause of half a minute or a minute the cough ceased, and the communication with the bottle was re-established. More air came from the chest and more coughing occurred, but not so much as before. The vacuum was again shut off, and after a pause again connected with the chest, and then the needle withdrawn, as no more air seemed to be obtainable from the pleural cavity. The signs of pneumo-thorax could not now be elicited, and the apex beat had come back at least an inch nearer its normal position. The patient would not confess that her breathing was easier for another ten minutes. At that time there was no doubt possible but that she was considerably relieved of her respiratory distress. From this time onwards the course of convalescence was normal.

In conclusion, let me say that so far as I can judge on theoretical grounds, and as a result of a very limited practical experience, Billington's operation for movable kidney is a very good one, perhaps the best yet described.

NOTES ON
FIFTY CASES OF NASAL DISCHARGE TREATED WITH VACCINES. (a)

By A. LOGAN TURNER, M.D., F.R.C.S.E.,
Surgeon, Ear and Throat Department, Royal Infirmary, Edinburgh,
AND
N. HAY BOLTON, M.B., Ch.B.,
Late Clinical Assistant, Ear and Throat Department.

The following fifty cases underwent one or more courses of treatment by vaccines. None of them have been specially selected with a view to publication here, but they form a continuous series. In some instances the condition had failed to respond favourably to other methods of treatment, while in others again, vaccines were used at the outset. In every case an autogenous vaccine was prepared. The opsonic index was not ascertained in any instance. As a rule, the injection was given once each week, and the treatment was carried out over a period of six to eight weeks, sometimes longer. If employed for a longer period than this, a second swab was taken from the nose and a fresh vaccine made from the organisms then found. The first dose was, as a rule, a small one, the second was double the first, and the third double the second, and so on.

The fifty cases treated in this way were grouped as follows:

1. *Cases of nasal catarrh*, eighteen in number; these included (*a*) eleven cases of chronic muco-purulent catarrh with or without some degree of nasal obstruction, also (*b*) seven cases of frequently recurring colds in the head.
2. *Cases of chronic purulent rhinitis*, nine in number; in a few of these slight crusting and commencing atrophy were noticeable.
3. *Cases of fœtid atrophic rhinitis* (*ozæna*), eighteen in number.
4. *Cases of accessory sinus suppuration*, five in number. In this group, with one exception, the vaccine was used only after operation as an adjunct in the after-treatment.

1. *Nasal catarrh.*—In the sub-group (*a*), eleven cases, we had to deal with the class of case in which there was a more or less persistent muco-purulent nasal secretion lasting in some cases for months, but in others for a number of years. Inferior turbinal engorgement caused a varying degree of nasal obstruction. In four of the cases there was an associated sycosis of the upper lip. Accessory sinus suppuration was excluded.

In the eleven cases comprising this sub-group, previous treatment had been carried out in nine, while in two, vaccines were employed at the outset. The treatment referred to consisted mainly in nasal douching; in three cases the galvano-cautery had been used and in one a partial turbinectomy had been performed. Because this treatment, however, failed to give the patients the desired relief vaccines were commenced. The organisms found in the nasal cavities in these cases were for the most part varieties of the staphylococcus pyogenes, also the pneumococcus, the streptococcus and the Bac. tetragenus. The results in this class of case were uniformly good. After an average of eight injections, the patients without exception expressed themselves as feeling better. Fewer handkerchiefs were used. The discharge disappeared or was greatly diminished in amount. In the four cases in which there was a secondary eruption upon the upper lip, this disappeared. In three of the cases a second vaccine was found necessary, some months after the first had been discontinued, because of recurrence of the symptoms. It is possible that some of the other cases may require further vaccine treatment, but at the present time they have not applied for it.

As an example of this class of case, we may quote the following: Female, chronic nasal catarrh with exacerbations and considerable nasal obstruction for some years. A mixed vaccine of the pneumococcus and streptococcus pyogenes was commenced. After four injections, she was breathing more freely, and after eight she felt very well and had no trouble with her breathing. An intercurrent cold was not so severe as had been the case before treatment was commenced. Six months after the twelfth and last injection, there had been no recurrence of symptoms.

In the sub-group (*b*) there were seven patients who complained of frequently recurrent acute

---

(*a*) Paper read before the Section of Rhino-Laryngology, at the International Medical Congress in London, August, 1913.

colds in the head. In two of the cases there was always very considerable elevation of temperature associated with the onset of the rhinitis. Sprays, douches, and even cautery treatment had been previously employed in some of them. The staphylococcus aureus and albus were the organisms most frequently met with, but the pneumococcus was also found. The vaccine was made from the nasal discharge at the time of an acute attack. There is no doubt that in these cases the acute attacks occurred with much less frequency and their severity was diminished. In four of the patients a second course of vaccines was carried out on account of recurrence of the acute catarrhal symptoms. As regards the three other patients in this sub-group, we have no notes regarding their further history. It is probable that in this class of case occasional courses of vaccine may be necessary.

2. *Nine cases of purulent rhinitis* with a tendency in some to a slight degree of crusting and atrophy. In this group of cases we had to deal with a condition of the nasal cavities which is generally recognised as the early stage or predisposing cause of atrophic rhinitis. The cases treated may be divided into two classes, (i.) three in which no improvement appeared to follow the injections. The organisms were the staphylococcus aureus and albus and a gram-bacillus in two of them. Nasal douching for a considerable period had failed to give relief. A course of vaccines for six weeks did not seem to improve the conditions. (ii.) In the six remaining cases, however, distinct improvement was soon observed and in five a cure may be said to have resulted; in one case, indeed, a year after the treatment, no nasal discharge could be detected. The staphylococcus aureus was present in the discharge in four cases, being in pure culture in two and combined with a short streptococcus in one and a gram-bacillus in another. The pneumococcus was present in pure culture in another case. Where more than one organism was present a mixed vaccine was given. Nasal douching had been previously tried in these cases without success.

3. *Eighteen cases of fœtid atrophic rhinitis* (*ozæna*).—In the light of the collective investigation into the nature of ozæna, the use of vaccines in this group of cases was of special interest. All the cases were characterised by crusting and some degree of atrophy of the mucous membrane; the fœtid character of the discharge was not recognisable in every instance, possibly on account of the syringing treatment that was being adopted, but there was no doubt as to the exact nature of these cases. In all of them nasal douching with or without preliminary plugging of the anterior nares had been carried out for varying periods of time from a few months to several years. A certain degree of benefit naturally accompanied the douching, but relapse took place on cessation of treatment.

The cases may be divided into two groups according to the results obtained by the use of vaccines: (i) in eight cases, no benefit appeared to be derived from the injections; (ii) while in ten others, more or less distinct improvement followed their use. It is necessary to analyse the two groups more carefully.

(i) Of the eight cases not benefited, the Bac. mucosus ozænæ (Abel) was cultivated and used in the vaccine in six, in pure culture in three, and associated with a staphylococcus in two, the Bac. proteus in one, and the Bac. pyocyaneus in one. In the remaining two cases mixed staphylococcal forms alone were procured. In these cases the maximum number of injections was six, the results not being sufficiently encouraging to warrant their further employment.

(ii) Of the ten cases in which vaccine treatment was undoubtedly followed by improvement, the Bac. mucosus ozænæ (Abel) was cultivated and employed in nine. In six a pure culture was obtained: in the remaining three it was associated with the streptococcus pyogenes and a diphtheroid bacillus in two, in one with the pneumococcus and staphylococcus aureus. In the tenth case a mixed culture of staphylococcus aureus and a gram-bacillus was obtained.

In nine cases, therefore, the vaccine contained Abel's bacillus, in six being used in pure culture. The number of injections varied from six to fourteen. The dose of the Abel's bacillus varied from 50,000,000 to 500,000,000 bacilli. The improvement that was noticeable alike to the patient and the observer varied in degree but was obvious in all. In five of the cases there was less crusting, less discharge, and an almost complete disappearance of the odour and the patient felt better. In five patients the crusting disappeared and in two of them the headaches ceased. In two, again, in whom there was no longer any crusting, some slight discharge remained. As regards the duration of this improvement, the following points were noted: two patients seen two months after the commencement of treatment showed no crusts, and no syringing was being carried out. One patient seen four months later had no crusts or odour, but a very slight discharge. One patient seen six months later had no discharge or crusting, and one had no discharge, odour, or headaches, eight months after the last injection.

4. In this group there are *five cases of accessory sinus suppuration.* In one case, left-sided frontal and maxillary sinus suppuration, no operation was performed, but the treatment consisted in nasal douching and the administration of a staphylococcal vaccine along with a gram-bacillus. After five injections had been given, there seemed to be some diminution in the amount of the discharge, but as the improvement was doubtful, the treatment was not continued.

In the remaining four cases, vaccines were employed after operative interferenze with the view of accelerating the healing. In one case of bilateral ethmoidal suppuration, after intra-nasal operation, a mixed vaccine of streptococcus pyogenes and staphylococcus aureus was administered. Six injections were given without improvement. In one case after the radical antral operation a vaccine was used, but it was of course difficult to estimate the part played by the vaccine. In a third case, in which an intra-nasal operation had been performed on the antrum, very little improvement followed lavage carried out for nearly three months. A staphylococcal vaccine was then used, improvement commenced and cure resulted. The fourth case was one of radical operation upon the frontal and ethmoidal cells, in which a fistulous opening persisted in the lower part of the incision for many weeks, apparently due to the persistence of some discharge from the ethmoidal region. A vaccine of the pneumo-bacillus was prepared and after three injections there was a marked change both in the character and amount of the discharge which gradually ceased and the wound permanently closed. Vaccines may prove a useful adjunct in the treatment of sinus suppuration after operation.

In conclusion we desire to express our sincere thanks to Dr. J. S. Fraser for permission to incorporate some of his cases in this paper and also to Dr. W. G. Porter and Dr. Ian Struthers Stewart for the use of three cases of ozæna under their care. Our thanks are also due to Dr. Shennan and the staff of the Pathological Department of the Royal Infirmary, Edinburgh, for the preparation of the vaccines.

PRESIDENTIAL ADDRESS ON CLINICAL PSYCHIATRY. (a)

By THEO. B. HYSLOP, M.D., C.M., F.R.S.E.

After thanking the Society for his election to the Presidential chair, the author remarked that the prevailing tendency for most thinkers is to endeavour to evolve the data of body and mind from other data derived from the study of embryology or epistemology, and with this tendency we must of necessity approve. A very little reflection, however, will show that evolution is only another name for transformation or change, and that, no matter how demonstrable and self-sufficing the demonstrable data of transformation may be, they do not deal with the phenomena of origin of the fundamental bases of life and mind on which the transformations evolve.

This tendency to evolve one thing from another has of necessity its limitations. Thus, for instance, the human mind cannot be regarded. or spoken of, in terms of energy; nor can we regard it as being a transformation of energy, for this would at once bring to the ground the fundamental dogma of science, that energy itself is indestructible and therefore incapable of conversion into anything other than energy. Here, therefore, we are forced to the conclusion that the phenomena of life and mind must be parallel in their collateral series of phenomena, and, since parallel lines do not meet, it therefore becomes inconceivable that either in time or space there ever was a beginning of the one, apart from a beginning of the other—if there ever really was a beginning of both or of either. The philosophical conclusion derived from the facts of physics and psychology is that mind in its ultimate essence is co-extensive in time and space with energy. With regard to the ultimate essence of mind or of matter, we must perforce be satisfied with hypotheses or conjectures, and it behoves us to recognise our limitations. With regard to the continued and earnest study of the phenomena of mind and energy in their parallel or apposite series of manifestations it is quite another matter, and it would be foolish to suppose that our conceptions as to the scope and extent of the connection may not in due course receive much further elucidation.

Clinical psychiatry is as a science still very young. Lugaro, in his memorable work on "Modern Problems in Psychiatry," points out that he whose custom it is to indulge in fatuous enthusiasm and pretentious language will possibly, at every inaugural discourse—either on the occasion of a congress in psychiatry, or at the opening of a conference—hail with a flourish of trumpets the tremendous progress made and the results accomplished, and extol the pre-eminence of psychiatry over other branches of clinical medicine; but there can be no doubt that the progress of psychiatry has been slow, laboured and rather unsatisfactory. That the science of psychiatry has not as yet attained such satisfactory results as those of surgery and several departments of medicine is not to be wondered at when we remember that psychiatry is not only a science of extreme complexity in itself, but it also embraces all the most intricate problems of biology and medicine. Lugaro fully appreciated this difficulty when he stated that the intimate contact which psychiatry assumes with the most varied doctrines and with the most diverse fields of social activity raises a host of current scientific, religious, metaphysical, philosophical and ethical prejudices against it, which paralyse its efforts and hamper its progress. Clinical psychiatry has the two-fold task of considering not only the psychic symptomatology of mental diseases, and this must, of necessity, go hand in hand with the study of normal psychology, but also the anatomical, physiological and pathological conditions which form the organic process or essential basis.

The history of clinical psychiatry consists in great part of the perhaps somewhat futile efforts of innumerable writers to bring within one comprehensive classification all the phenomena of mind and brain, taking note of the data of development, mental and physiological symptomatology, together with the various factors of causation. Little wonder is it, therefore, that each new classification, instead of leading to real progress and clearness of understanding, has but added to the prevailing confusion and obscured the issues of greater importance. Thus it is that many of the more recent works on clinical psychiatry, whilst possibly adding to the sum of our knowledge, have oftentimes been merely repetitions of data already acquired, but played out in new hands after a re-shuffling of the cards. To this tendency in modern psychiatry, the benefit to be accrued is apt to be negatived by the confusion and delay so occasioned. Our danger appears to be, when dealing with the human mind and body, lest we should think in text-book terms and thereby tend to lose sight of processes. I would express this more tersely by stating that mere labelling does not imply delivery. Within the last few years some of the riddles of the psychoses have been newly propounded through the medium of Freud, of Vienna, and undoubtedly his methods have in some instances led to a more thorough understanding of the origin and development of various abnormal mental states. To Bleuler, Jung and their co-workers at Zurich and to many others of the Freudian school we are indebted for further elucidation by analysis of many psychical problems. I will not anticipate events, however, as one of our meetings this session will be devoted to the subject of Freud and his School of Investigation.

When we review the data of physiology of the nervous system, we see how much we have been indebted to experimental destruction or excitation of macroscopical parts accessible by vivisection. Microscopical anatomy has also advanced to such an extent that individual morphological types of nerve cells have been not only recognised, but have also occasioned many vague conjectures as to their nature. The homologies of structure of the cells in the cerebral cortex have led some observers to conclude that in the nervous system there are no two cells, nor any two fibres possessing absolutely identical function. That the cerebral cortex is a vast field for further pathological research no one will deny, and it is possible that in the future we may yet be able to draw more satisfactory inferences regarding the functions of single units than we should be justified in doing to-day.

By means of macroscopical and microscopical research, we are now in possession of innumerable data in connection with the nervous system and its cellular units or neurones, but here again we must patiently await the results of further investigations before venturing to generalise. It may be stated with truth that up to the present the anatomical facts already noted, instead of elucidating the problems as to the physical basis of mental processes, tend rather to increase our difficulty in understanding the complex mechanism of the nervous system.

In a paper read before this society in May last year, I endeavoured to demonstrate to you some considerations as to the intracranial mechanism in health and disease, and it seemed to me that by the adoption of a preliminary mechanical and mathematical method of study of the cranial contents, we might be enabled thereby to gain a more rational and intelligent appreciation of some of the apparently most difficult of the problems of clinical psychiatry.

(a) Delivered before the Chelsea Clinical Society at the meeting held at St. George's Hospital, October 21st, 1913.

The usefulness of applying these mechanical and mathematical principles for the explanation of intracranial disease is evidenced in a remarkable degree when we study the disturbances from which the brain and its adnexa are prone to suffer. Thus, arterial inflammatory affections, capillary engorgements, and increase of serous exudation and diapedesis of leucocytes, with ultimate formation of connective tissues, can be represented by more or less definite formulæ. Similarly, alterations in the relative proportions of the lymph as a whole or in its relationship to individual units such as the neurons can be defined in mathematical terms, and, lastly, the processes of excretion by the lymphatics, the venules, veins and sinuses may be considered either separately or in their entirety. Intracranial physics has not yet elaborated the mechanism of backward pressure in the vascular structures, and seldom do we find anything in treatises on diseases of the brain which tends to throw much light upon the mechanism or results of backward venous pressure. We know that venous congestion and stasis do occur, and that the surface veins of the brain are in almost immediate juxtaposition to various brain centres, but the variations in venous pressure and their effects on the cortex as occurring in health and disease have as yet been scarcely touched upon. We have here, therefore, an almost unexplored field for research.

Neurasthenia, a Disease of Civilisation.

From the clinical standpoint, there would appear to be no affection, or group symptoms, or syndrome, more prevalent or more likely to become more increasingly prevalent, than that of neurasthenia. It is a disease of civilisation, and it is also, in my opinion, a warning that over-pressure, when combined with defective bodily health, can have but one result, viz., degeneration. A quarter of a century of study of mental and nervous ill-health has taught me one great truth, viz., the nervous system is in itself capable of vast and continued exertion so long as it is properly and efficiently served by the body mechanism of waste and repair. Needless to say, the finer and the more sensitive the nervous mechanism, the greater the need for the careful regulation of its nutritive and excretory processes. Over and over again is this exemplified in connection with some forms of nervous and mental disorder, which are regarded as hereditary and therefore incurable, whereas the disorders are in reality but due to the hereditary defects of the bodily mechanism whereby the waste and repair of the nervous system are duly affected.

The truth of this statement is exemplified in families which suffer from glandular anomalies with imperfect balance of the nutritional and metabolical processes. The thyroid and the parathyroid] apparatus are still so much discussed by physiologists that we are as yet unable to formulate definite views as to their functions in the bodily economy, but we are nevertheless fully aware of their importance in maintaining health. Undoubtedly many forms of psychoses, both alternating, progressive, and permanent, may be traced to defects in these or other glands; the nervous system itself being merely a participant in the general metabolic defect. Speaking generally, it may with a certain degree of certainty be stated that all the rhythmical, alternating and intermittent psychoses are due to faults in the mechanism of waste and repair as determined by the various organs of secretion and excretion. Since advancing this theory in a paper read before the Harveian Society some years ago, I have become more and more satisfied with its truth, and I do not think it is too positive an assertion to make when I state that every form of psychosis which is rhythmical or alternating in its occurrence is somatic and extracranial in its origin.

Health or Perversion of Cerebral Functions.

The circulatory system is the means whereby nutrition and cerebral metabolism are duly effected, and in their relationship to the general circulation the contents of the cranium hold a somewhat similar position to those of the pelvis, or even the limbs. It is a common observation that venous congestion of the pelvic viscera is a usual accompaniment of diminished blood pressure, and this is also attended by diminished activities within the viscera, as evidenced by deficient peristalsis, constipation, etc., etc. It is now granted by many clinicians that somewhat similar venous congestive stasis pertains in the limbs and other regions, and even in the cranium itself. I have dealt elsewhere in detail with the mechanism of the intracranial contents and have shown how increase of the fluid contents of the cranium becomes possible only by compensatory diminution of other of the fluid contents. In a previous paper read before this society, I pointed out that the cranial cavity may be compared to that of a hose syringe, the perforations at its nozzle corresponding to the usual points of egress for the fluids (*i.e.*, the normal channels into the veins, lymphatics, and the spinal column). If we close some of the numerous orifices at the base of the skull normal conditions are able to resist the outflow of fluids from the cranium. Any displacement of fluid takes place along the lines of least resistance, and it will pass out of the skull in physiological conditions of health. If, however, this process of displacement is arrested, the fluid then seeks to escape from the points of lesser resistance, and the phenomena of dizziness, ringing in the ears, flashes of light, rhinorrhœa, choked disc, etc., are occasioned, the intracranial fluid seeking to escape by unusual channels.

Certain it is that in many of the cases of neurasthenia studied by me the general blood pressure has been subnormal and the clinical symptoms have been such as would arise in consequence of venous congestion of the various orifices of egress from the skull. Any diminution in the force of the arterial wave is attended by a corresponding sluggishness in the venous return, and it is to the various groups or syndromes of symptoms thereby occasioned that we usually apply the term neurasthenia. It would take up too much of the time available were I to attempt to deal in detail with the various conditions determined by venous congestion of the various orifices of the skull. I have but to mention hæmatoma auris, adenoids, etc., to show the wide scope of the enquiry. I would, however, make brief reference to the comparatively rare conditions of blocking of the small emissary vein of Santorini in association with thrombosis of the lateral sinus. I have seen this occur in several instances. In one instance, the occurrence of swelling over the mastoid region was followed by relief from acute mania, but only to relapse again to the maniacal state on the subsidence of the swelling.

Venous Congestion and Stasis.

That venous congestion and even stasis is much more common in insanity than is generally supposed is borne out by Mott ("Croonian Lectures," 1900, p. 50), who, in referring to the conditions of the disease, said that "in most instances a striking naked-eye feature was the distension of the veins with blood, and frequently there was sub-pial hæmorrhage; also the peri-vascular lymphatics were usually distended with fluid. No doubt both the increase of blood in the superficial veins, the increase of fluid in the peri-vascular lymphatics, and the general œdema of the brain itself, were proportional and compensatory to the diminution of the arterial blood. The arteries were generally empty, likewise the capillaries. In some cases the peri-vascular lymphatics and membranes were the seat of a marked cellular infiltration resembling the condition found in general paralysis. Collateral circulation to the medulla, by which the respiratory centre is kept going, is essential to life. Such collateral circulation when established—and if the animal lives it must have been established—would be accompanied by blood-supply to the choroid plexus, and the cerebro-spinal fluid, which functions as the lymph of the brain, would consequently be secreted in abundance and soon compensate for the diminution caused by the failure of the arterial circulation. Thus the increase of cerebro-spinal fluid would account for the œdema of the brain, the dropsical condition of the cells, and the dilatation of peri-vascular lymphatics.

In reference to the effects of cerebral anæmia experimentally produced, he says (*op. cit.* pp. 52 and 53) : "Arteries in this disease are seldom occluded, whereas congestive stasis in the arterioles, capillaries, and veins is common, even thrombosis in the latter may occur ; and we may consider that the destruction of the nervous tissue of the cortex may be accelerated by inflammatory stasis. It is curious how general it is to find the brain atrophy in this disease limited particularly to the frontal and central convolutions, whereas the occipital and temporal lobes escape in great measure. Over the atrophied regions the pia-arachnoid membrane is thickened and adherent. Many observers, including Flechsig and Mickle, consider that the region of atrophy and pia-arachnoid thickening more closely corresponds with the distribution of veins which open into the longitudinal sinus, and from a large number of observations made by myself and my assistants, I have come to the conclusion that venous congestive stasis in that portion of the brain plays an important part in the symptomatology and pathology of general paralysis."

Full credit must be given to Mott for his most valuable and suggestive work in this direction, and my own observations entirely agree with his, that venous congestion does play an important part in the production of congestive, epileptiform and apoplectiform seizures of general paralysis, as is shown by the fact that a brisk purge or an enema will often prevent or cut short these seizures, presumably by relieving frontal congestion and general venous turgescence.

With regard to clinical psychiatry, we are well aware that hallucinations of hearing are not only exceedingly common in their occurrence, but they also form an element of serious import in regard to the development and course of the insanity. The reason for this is to be sought in the fact that not only is the sense of hearing the least protected, but the region of the brain in which its centre is situate is the region of greatest wear and tear and the region where arterial and venous derangements are most likely to occur. This is exemplified by the clinical fact that in toxic or other defective states perversions of hearing are not only some of the earliest symptoms to appear, but they are the last to disappear, and they are certainly the most difficult to treat. In this connection, I may state that so seriously do I regard these hallucinations that I have been in the habit of treating them by the apparently heroic method of procuring complete rest of the auditory centres by the induction of deafness by the simple means of plugging the auditory meatus with a suitably devised plug of ordinary paraffin wax. The results obtained by this method have been in most instances remarkable, and in the course of three or four days the hallucinations have usually entirely disappeared.

In these few remarks I am fully aware how limited has been the scope of my address, and there are innumerable questions which it might be fitting to discuss, but it is obviously quite impossible to here elaborate a field of enquiry which is fraught with such extreme difficulty in almost every conceivable direction. I will conclude, therefore, with the personal statement that with regard to clinical psychiatry, the longer I live and the greater my experience, the more do I come to see that the human brain is capable of almost infinite vigour and development so long as it is faithfully served by the body to which it must look for its nourishment and repair. If perchance the human mind is to be capable of manifesting itself in its fulness, depth and vigour, it needs must have for its instrument a bodily mechanism which shall serve it faithfully and well.

I have dealt somewhat in detail with these conditions of venous congestion and stasis, because it appears to me that whereas the brain convolutions, in their relationships to arterial blood-supply, have been so fully discussed, the venous drainage has received but scant attention. The temptation to enter upon a full description of the venous drainage from the various convolutions is great, but for present purposes it would be too lengthy an undertaking. Suffice it to say that careful consideration of the mechanics of the intracranial circulation and the relationships of the systems of drainage to the various cortical areas has gradually enabled me to formulate a series of syndromes, based mainly upon the conditions of venous drainage from the various convolutions. That these syndromes have anatomical and pathological explanations which are borne out by observation and by the effects of appropriate treatment it will be my endeavour to prove in a more extensive way elsewhere.

OPERATING THEATRES.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

Operation for Deformity Resulting from Fracture of the Femur.—Mr. Jackson Clarke operated on a man, æt. 35, who had been admitted with a history that some years ago he had sustained a fracture of both thigh bones in the following manner : He was seeking sea birds' eggs on the cliffs at Anglesea, and slipping over the edge at a point where the rocky cliff face was vertical and, according to the patient's statement, over 80 feet in height, he fell. In falling he kept upright, alighting on his feet upon hard rock ; he then fell forward and lay helpless. He maintained consciousness throughout, and the result of immediate treatment left him very lame, unable to go upstairs or mount a ladder, and so incapacitated from following his occupation (a lighthouse keeper).

On examination at the hospital, some four or five years after the accident, the right great trochanter was found to be elevated two inches above its normal position and the right thigh to be adducted. The left femur had been broken just below its middle, and the fragments had united firmly, the fragments being inclined at an angle of 40°, salient outwards. Radiographic examination showed that the head of the right femur had been cut off flush with the rim of the acetabulum, and that the fragments of the fractured left femur were solidly united by a spherical mass of new bone.

First Operation.—The patient at first only desired the right hip to be operated on, and this was done with the view of securing some co-aptation of the upper end of the femur and the acetabulum, as well as of removing the adduction. For the latter purpose the adductor longus was divided near its origin. The region of the hip-joint was then exposed by an anterior incision, the upper part of which was prolonged backwards just below the iliac crest. By dissection through this incision the tensor fasciæ femoris and the fore parts of the gluteus medius and the gluteus minimus were turned down, the rectus and sartorius being drawn inwards ; the upper and front parts of the capsule of the joint were thus fully exposed. The joint was then opened by an incision between the two parts of the Y ligament. On retracting the lips of this capsular incision, both the acetabulum and the inner and upper ends of the femur were fully exposed. The neck of the bone had been totally absorbed except for a small spur at its lowest part. The head of the bone had also undergone some absorption. On abducting the limb and making traction thereon it was found that the spur-like remains of the neck could be made to enter the acetabulum, and after the latter had been somewhat deepened by scraping, the limb being maintained in the abducted position, the capsule was sewn up by catgut sutures, as was also the remainder of the wound. The limb was put up in the abducted position. The patient's convalescence was uneventful, and at the end of a few weeks he was walking about. He found that he could go upstairs, which he could not do before. He soon left the hospital.

The effects of the first operation were so good that the patient came back a year later to have his left femur operated on.

Second Operation.—An incision was made on the outer aspect of the left thigh with the convexity backwards; a flap was raised up of skin and fasciæ, exposing the anterior border of the vastus externus, this muscle was separated from the cruræus, and the latter incised down to the bone. The region of the fracture was then cleared by means of a rugine, a wedge of bone was now taken away by means of saw and chisel, the base of the wedge being external. Two four-hole Lane's plates were selected, adjusted to the surface of the bone and fixed by two screws each; the soft parts were then drawn together by means of catgut sutures, and the limb put up on a long outside splint, supported by three malleable steel splints adjusted to the outer surface of the dressing.

Convalescence was again uneventful, and at the end of the third week a single Thomas's hip splint was applied in place of the other splints. At the end of the seventh week, a firm mass of callus having formed, the patient was allowed to stand. The thigh is now in its proper line, and it is probable that the patient will be able to resume his occupation.

Mr. Jackson Clarke said that the second operation was an example of the operative *technique* introduced by Sir Arbuthnot Lane, and emphasis should be laid on some points, such as a faultless asepsis, a free incision to give ample access to the parts, the muscles being separated as far as possible rather than divided, and when their division is inevitable it should be done at as great a distance as possible from their supplying nerves; it was for this reason that the cruræus was incised towards its outer part. Finally he insisted upon the importance of restoring not only the muscles but also the fasciæ by means of catgut sutures.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

Meeting held November 14th, 1913.

Mr. Charters J. Symonds, President, in the Chair.

EXHIBITION OF CLINICAL CASES.

Dr. A. M. Gossage showed a case of subcutaneous granulomata. It was that of a girl, æt. 3½, who was admitted into hospital on August 12th last for stiffness in the left knee and pain and stiffness in the left wrist. At the age of two her mother noticed that the left knee was held stiff and slightly bent so as to make her walk awkwardly. Lately this had been worse, and the child frequently wanted to rest. Three days before admission the left hand was noticed to be doubled up, and she complained of pain in her wrist. No lumps had been noticed in the trunk or head.

On admission she was found to be a healthy-looking child. The left wrist was flexed, and the dorsum of the left hand was somewhat swollen; anteriorly over the tendons at the wrist there was some reddish discoloration, and there was some thickening under the skin. The child was unable voluntarily to extend the hand and fingers, whilst forcible extension caused pain. There were about twenty subcutaneous nodules, from the size of a millet seed up to a small pea, under the skin of the scalp, neck, and trunk. The left knee was apparently normal, and no other abnormality could be found elsewhere.

In the night of August 29th there appeared pain and swelling in front of the right wrist, with flexion of the wrist and some swelling in the dorsum of the hand. On examination a precisely similar condition was found to that in the left wrist—*i.e.*, some thickening and discoloration of the skin, and subcutaneous swelling, which appeared to be formed of several nodules matted together, with involvement of the subjacent tendons.

On September 16th it was noticed that the right knee was sometimes drawn up, and that the child seemed unable to straighten the leg again, but forcible replacement by the nurse caused no pain, and the knee subsequently seemed normal and there was no swelling.

There was no alteration in the condition until October 3rd, when she was ordered pot. iod. 3 gr., t.d.s. Since then the tumours had got smaller and many had disappeared, whilst the swelling in front of the wrists had diminished, and the movements of the hands and wrists had become painless and more free.

On September 9th two of the tumours were cut out, and were subsequently examined by Dr. Hebb, who reported as follows: "Both tumours are surrounded by a zone of connective tissue in which are reticular histological tubercles with numerous large giant cells. The central areas are filled with some homogeneous substance which is crowded with small cells of irregular shape; also certain bodies, somewhat resembling in appearance Charcot-Leyden crystals," are demonstrable by the Ziehl-Nielson method. The nature of the growth was uncertain. No organisms were discovered. The tumours having been put directly into formalin, no culture could be made for them.

The Wassermann and von Pirquet reactions were both negative.

Dr. Gossage said that the three probable causes for granulomata of this type were: (1) syphilis, (2) tubercle, and (3) sporotrichosis. There was nothing in family or personal history to suggest syphilis, and with a negative Wassermann reaction this might be excluded. The histological appearances, the rapid improvement with iodide of potassium, and the negative von Pirquet reaction similarly weighed against the diagnosis of tubercle. In the absence of a culture of the organism one could not be certain of the diagnosis of sporotrichosis, but this seemed to be that which was most probably correct. It was to be noticed that there was no tendency for the tumours to break down in the two months before treatment with iodide was commenced.

Mr. W. J. Midelton showed two cases of arthritis deformans treated by continuous counter-irritation. Woman, æt. 60. Sixteen years ago she first noticed rheumatic symptoms; the joints of the fingers, knees, and ankles eventually became markedly swollen up to two years ago in spite of treatment. Severe attacks of sciatica occurred at times. The patient was first seen by Mr. Midelton with a view to treatment two years ago. At that time she was very depressed, and in much pain. Salicylates relieved the latter somewhat, but increased the depression. On examination the patient was found to be too thin; all the phalangeal joints were swollen and of the rheumatoid type. The fingers were cyanosed. The knees and ankles showed enlargement of a soft character with little or no bony change. There were soft pads beneath the ligamenta patellæ bulging on each side. The legs were slightly œdematous. There was a fibrous nodule at the back of the proximal phalanx of the left thumb, about the size of a small hazel-nut and very hard. Subcutaneous tissue of legs thickened, and suggestive of myxœdema. The toes were cyanosed and the nails withered very much, having practically disappeared in several instances. Very few teeth remained; the patient had obviously suffered for many years from pyorrhœa alveolaris, and the teeth had in most instances become so loose as to need extraction. No marked affection of heart or lungs was found, but the stomach and bowels were thought to be atonic. Treatment by means of continuous counter-irritation was commenced on September 27th, 1911. October 31st: Swelling gone from fingers and tenderness from feet. Eventually became so well and active that she undertook strenuous work; on her feet all day, and out socially at night. She had had slight recurrences from time to time, but the treatment always readily subdued them, and the patient remained well and active. The pads had gone from beneath the patellar ligaments, the nodule from the thumb. She was wearing shoes that had been put aside for years. Her attacks of sciatica were now slight. The toe-nails had grown again. Excessive fatigue contributed more to recurrences than anything else.

II.—A woman, æt. 54. Five years ago the ankles swelled; at about the same time she had a "paralytic seizure"; the right arm and left leg and back of neck being effected. There was difficulty in moving the head and much pain. Her walking power gradually returned but was variable. She suffered from syncopal attacks, with, at times, actual loss of consciousness lasting two hours. The attacks had increased in severity. All the joints were more or less tender and stiff but not much swollen. There was loss of muscular power in the knees, their flexion and extension being limited. The right elbow and neck were very tender. A typical rheumatoid condition of the first and second metacarpophalangeal joints was present. The skin of four fingers was glossy, the wrists were puffy but moved fairly well, she was scarcely able to move the head at all, the features being mask-like; the right arm was practically useless. Teeth: many out, remainder infected at roots. Treatment by continuous counter-irritation was commenced in February, 1912. The patient had not been out of the house for four months when first seen, and a very gloomy prognosis had been given. The heart had been thought to be in an advanced state of fatty degeneration. Within a very short time after the commencement of treatment by means of counter-irritation the patient greatly improved. She regained power to write, sew, walk up and down stairs easily, etc. The patient had become increasingly active and had practically ceased to have any syncopal attacks; she still had treatment from time to time.

Dr. F. Parkes Weber showed a case of rheumatic nodules associated with rheumatic torticollis. The patient, æt. 11, was a pale, rather delicate-looking boy with a certain degree of wry-neck, the neck being bent towards the patient's right with the chin turned a little to the left, and there was no arthritis, nor did the boy complain of any pain or tenderness anywhere, but there was some puffiness about the second and third metacarpo-phalangeal joints in both hands, and over these joints very small rheumatic nodules could be seen and felt. There were moderate-sized rheumatic nodules over both elbows and both knees, those over the knees being the largest and the most numerous. The olecranon bursa at both elbows was enlarged. The heart was excitable in action and the impurity of the first sound at the apex suggested slight endocardial changes at the mitral valve. In the absence of fever the frequency as well as the excitability of the heart's action suggested slight myocardial implication. There was a variable systolic murmur to be heard over the "pulmonary area." Some of the lymphatic glands in the neck were a little enlarged.

The history was that the boy enjoyed good health until the present illness commenced on September 13th, 1913, with a pain in the left ankle; this joint became swollen on the following day. He was treated by rest in bed and small doses of salicylates.

The wry-neck appeared at the end of September, and was at first accompanied by a little pain at the lower posterior part of the right side of the neck. The rheumatic nodules were first noticed in the middle of October, at first only on the elbows and knees, later over the hands also. Recently he had been treated with subcutaneous injections of rheumatism "phylacogen," and with careful massage of the neck. Röntgen-ray examination showed no bony change in the neck. The special interest of the present case was the association of the wry-neck with rheumatic nodules and affection of the olecranon bursæ, suggesting that a kind of true "rheumatic fibrosis," analogous to that which produced rheumatic nodules over the periosteum and fibrous structures, was the cause of the wry-neck.

Dr. F. Parkes Weber also showed a case of angiokeratoma with bony changes. The patient, æt. 16, was a physically rather under-grown and under-developed boy, mentally quite normal. His extremities were inclined to be cyanosed, and in winter, since the age of 4, he had suffered severely from chilblains of the hands and feet, which had left a good deal of scarring. Owing to these cicatricial changes, the movement in some of the terminal finger-joints and in the toes had become very limited. On the hands were a number of dirty-reddish spots which were minute warts on angiomatous (telangiectatic) bases; they added a peculiar speckled appearance to the cicatrisation resulting from the chilblains. On the feet, in addition to the scarring of the toes from chilblains, there were a number of large hard "corns" (keratoma); some of these resembled the callosities which occasionally preceded perforating ulcers. In the Röntgen-ray skiagrams of the hands and feet, the terminal phalanges of the hands appeared somewhat stunted, and there was slight general rarefaction of all the handbones; in the feet there was marked deformity of the terminal phalanges, and there was more rarefaction of the bones than in the hands; the distal portion of the terminal phalanx of the left big toe had disappeared, as if by a process of absorption, like that sometimes seen in Raynaud's disease. In spite, however, of the tendency to cyanosis of the extremities, the patient had never had any definite attacks of Raynaud's phenomena. The knee-jerks were exaggerated, but there were no signs of syringomyelia or other organic nervous diseases. Nor was there evidence of disease of any of the abdominal or thoracic viscera.

The chilblain-like condition ordinarily associated with angiokeratoma of the hands and feet seemed to him insufficient in the present case to account for the bony changes revealed by Röntgen-ray examination; and yet there had been no definite attacks of Raynaud's phenomena nor local tuberculous disease to account for them.

Dr. W. Essex Wynter showed a case of hæmophilia. The patient, a man, æt. 22, was admitted to hospital in November, 1913, for hæmaturia. There were four sons, of whom patient was the youngest, and no daughters. The eldest and second were both alive and well. The third died at the age of 15. He was a bleeder. The patient remembered his once cutting his thumb, which bled for days and led to his being admitted to hospital. He also had, occasionally, swelling of joints which lasted some weeks. The patient himself, before he was æt. 8 partly remembered and had been told that he had frequently painful swellings in the knees which necessitated his staying in bed, but always cleared up eventually. When æt. 9, he had an attack of hæmaturia, unaccompanied by pain, which kept him in bed for fourteen days.

The present attack of hæmaturia commenced ten days before admission with slight coloration, which gradually became more intense. The following day there was an attack of pain shooting down to the groin on the right side and lasting half-an-hour. Swelling of the right elbow commenced a week before admission accompanied by stiffness and some redness, a similar attack having occurred a month previously. When shown the patient was a healthy-looking youth with bright complexion and was well nourished. There was some swelling and limitation of movement in the right elbow and ecchymosis of the skin in the outer and flexor aspect. The urine was almost porter coloured and opaque, specific gravity 1020, acid, and contained albumin corresponding with the blood. Corpuscles were present in quantity. An X-ray examination disclosed no stone, nor any enlargement of kidneys. The organs appeared quite normal, and apart from the hæmorrhage there was no sign or feeling of illness.

Dr. J. H. Drysdale and Mr. G. E. Gask showed a case of splenic anæmia; splenectomy. Hæmatemesis eighteen months after the operation. The boy, æt. 16, was admitted to hospital in December, 1911, for hæmatemesis and enlargement of the spleen.

Two years before admission he first noticed a large lump in the left side of the abdomen. Since then he had gradually become paler and had been subject to attacks of giddiness. Four months and again two months before admission he vomited up a large amount of blood.

On admission the spleen was found to be much enlarged. Red cells, 3,525,000; hæmoglobin, 45 per cent.; colour index, 0.64; poikilocytosis; polychromatophilia present; whites, 3,000; all forms diminished in numbers; a few myelocytes. Wassermann's reaction was negative.

January, 1912: The spleen was excised by Mr. Gask, along with two or three spleniculi.

March: Red cells, 3,900,000; hæmoglobin, 54 per cent; colour index, 0.7; white, 6,400; polymorphonuclears, 2,816; lymphocytes, 2,816; large mononuclears, 678; eosinophiles, 38, and basophiles, 114 per cubic millimetre.

He remained in good health till July of this year, when he vomited more than a pint of blood and fainted. He slowly recovered, and in September, after a short fit of coughing, brought up a thick silk ligature.

He was readmitted in October.

His blood count now was: Red cells, 5,400,000; hæmoglobin, 90 per cent.; colour index, 0.83; whites, 6,600; polymorphonuclears, 2,574; lymphocytes, 3,630; large mononuclears, 99; eosinophiles, 198, and basophiles, 99 per cubic millimetre; no nucleated reds or myelocytes were seen. The red cells showed excessive variations in size and depth of staining reaction. Poikilocytes were numerous; reticulate cells 1.8 per cent.; fragility:—hæmolysis began between 0.45 and 0.4 and was not complete before 0.3.

The interest of the case lay in the recurrence of the hæmatemesis eighteen months after the removal of the spleen. Patients with splenic anæmia might live for twenty or thirty years without surgical interference, and they died sometimes as the result of operation. If they were to remain liable to attacks of hæmatemesis—which was, after all, their most dangerous symptom after splenectomy had been performed—it raised the question as to how far the operation was advisable. This patient was not cured of his disease, for apart from the attack of hæmatemesis he still had a leucopænia, his polymorphonuclears were only half the proper number, and many of his red cells showed abnormalities. His general condition was certainly improved, but one was precluded from saying that his life was safe from the dangers of splenic anæmia.

Dr. Arthur F. Hertz and Mr. D. W. Johnson showed a case of cervical rib with marked vascular symptoms in a woman, æt. 45, and a case of myatonia congenita in a boy at 3½ years.

Mr. C. A. Ballance showed a woman, æt. 20, whose facial paralysis had been treated by facio-hypoglossal anastomosis (end to end), and end to end anastomosis of the descendens noni to the hypoglossal.

Mr. W. H. Battle showed a case of microglossia in a child æt. 1 year and 5 months.

Dr. Albert Wilson read a short paper on the treatment of syphilis by ars-acetin and by excision of the primary sore.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Clinical Meeting held in the Royal Infirmary, Wednesday, November 19th, 1913.

The Vice-President, Dr. Melville Dunlop, in the Chair.

Dr. Dawson Turner showed a case of nævus and a case of cheloid under treatment by radium.

Dr. Norman Walker showed a case of nævus and a case of dermatitis autophyta.

Dr. J. D. Comrie showed a child, æt. 7, suffering from spastic paraplegia. She could stand, but was unable to walk. Intelligence was good and the arms were strong. The lesion was probably a congenital defect at the upper end of each Rolandic area.

Dr. R. A. Fleming showed two cases of beri-beri, one of wet and the other of dry type.

Dr. Edwin Bramwell showed two brothers who suffered from progressive difficulty in walking, with spastic paraplegia, intention tremors, and defective articulation. The cases were intermediate between Friedreich's ataxia and family spastic paraplegia.

Dr. Gulland showed four cases of aneurysm.

Mr. John Fraser showed a child, six months old, in whom he had transplanted a portion of the fibula to make good a congenital deficiency of the tibia on the opposite side.

Mr. Beesly showed a patient after interscapulothoracic amputation for tuberculous disease with sinuses. The shoulder-joint had been excised for tuberculous disease two years before, and the arm had been useful for two years before disease recurred.

Mr. Wallace showed a case of diastasis of the lower end of the femur after plating; and a man, æt. 46, after resection of the middle portion of the stomach for carcinoma.

Mr. Wilkie showed a boy, æt. 8, suffering from osteo-chondritis deformans juvenilis. The condition was probably due to an accidental interference with the blood supply of the head of the femur, and after two or three years recovery might be expected.

Mr. Dowden showed two cases of fracture of both bones of the leg which had been treated by hanging the legs over the end of the bed without splints. There had been marked shortening before the treatment. There was great œdema. In one case union was somewhat delayed, in the other union was rapid. The result in both cases was good.

Mr. George Chiene showed a woman, æt. 42, who had suffered from symptoms of intestinal obstruction. The condition found was strangulation of an epiploic appendix in a subsidiary peritoneal pouch.

Mr. Struthers showed a man suffering from deformities due to ostitis fibrosa; and a boy, æt. 9, who first had symptoms of Jacksonian epilepsy and then generalised epilepsy. He had remained well for seven months after trephining, although nothing to account for the fits had been found.

Mr. Cathcart showed a man after operation for tuberculous glands in the neck, where the internal jugular vein was torn close to the skull and closed by plugging.

Mr. Cathcart also showed a man finally cured of recurrent fibroid tumours of the neck and face after six operations. Carcinoma of the splenic flexure of the colon afterwards developed.

LIVERPOOL MEDICAL INSTITUTION.

The First Pathological Meeting of the Session, held on November 13th, 1913.

Mr. F. T. Paul, F.R.C.S., in the Chair.

The following specimens were shown and described:—

Mr. R. W. Murray: (1) Large sacculated popliteal aneurysm from the amputated limb of a man 56 years of age; (2) the amputated leg of a woman 50 years of age with elephantiasis, the limb after amputation weighed 64 lbs. The patient had never been out of this country, and had carried on her work as a washerwoman up to the time of her admission to hospital.

Mr. Adair Dighton showed sections illustrating sarcoma of the nose, one section being of the nasal tumour and the other of the glands in the neck.

Dr. Stopford Taylor and Dr. MacKenna showed a nasal polypus of tuberculous origin.

Mr. Newbolt showed (1) myxoma of the parotid; (2) epithelioma of the jaw.

Mr. Kelly and Professor Ernest Glynn showed (1) some specimens from three cases of abdominal trauma. They included ruptured liver, ruptured spleen, fat necrosis, etc. Mr. Kelly considered that the rectus aponeurosis was the best material to use for suturing the liver; this material did not cut through. (2) Carcinoma of the pylorus removed at operation; (3) a congenital cystic kidney; (4) a suicidal gun-shot wound of the skull.

Dr. Abram and Professor Ernest Glynn showed a specimen of polyposis intestini adenomatosa in a girl, associated with chronic diarrhœa. One portion had developed into columnar cancer with metastases in the liver.

Professor Ernest Glynn showed (1) tuberculosis in the lung of a camel; (2) tuberculosis in the pericardium of an ox; (3) melanoma in the liver of a horse; (4) perihepatitis in a horse; (5) nutmeg liver in a pig.

Dr. Nathan Raw showed (1) a specimen of acute tuberculous pericarditis in an adult aged 30, secondary to miliary tuberculosis of the lungs. During life 40 ounces of fluid were withdrawn by paracentesis, with marked temporary benefit; (2) a lung showing healed tuberculosis in the upper lobe. The man, aged 59, died from acute pneumonia, (but had consumption when 35 years of age and had been quite cured.

Mr. Douglas Crawford showed (1) endothelioma of testicle; (2) foreign body (brooch) from intestine. Cotton wool had been administered, and the brooch had been passed wrapped up in it.

Mr. R. C. Dun showed (1) microscopical section of congenital fibroma of the finger, removed from an infant 9 weeks old. The tumour was the size of a cherry, pedunculated, and grew from the palmar surface of the digit; (2) microscopical section of wall of bronchial cyst. The lining consisted of stratified epithelium, and typical masses of lymphoid tissue were present. The cyst was removed from a boy aged 12 years. It occupied the position of the 2nd bronchial cleft—it was the size of a tangerine orange, and had only been noticed for twelve months.

The specimens were discussed by Mr. Paul, Mr. Douglas Crawford, Professor Ernest Glynn, Mr. Yorke, and Dr. Blair Bell.

Mr. K. W. Monsarrat and Dr. I. J. Williams read a paper on

INTRAMURAL EXTENSION IN RECTAL CANCER.

The paper presented the results of complete histological examination of the specimens derived from four cases of operation for rectal cancer. The specimens were cut in serial sections, and the staining method employed was mucicarmine and hæmatoxylin. It was considered that it was incorrect to look upon mucin as a degeneration product, or its presence indicative of growth ineffective from the point of view of metastases. It was shown in the observations reported that infiltration was widest in the planes of the longitudinal muscular coat and the cellular tissue outside it. No permeation of lymphatic plexuses to a distance beyond the primary site was demonstrated. In particular it was not found that permeation took place in the plane between the bases of the follicles and the muscularis mucosæ.

In one of the specimens it was shown that the growth was present within the venules in the muscular coat and the adventitia. The specimens were representative of the commonest type of rectal cancer—a fibrous stenosing carcinoma. They went to show that the disease remained local for a considerable period, that glandular invasion might be considerably delayed, and that longitudinal extension in the rectum was not rapid and wide, but comparatively slow and restricted. The authors considered that while abdomino-perineal amputation was the operation of choice for carcinoma, resections and amputations less extensive than this procedure offered fair prospects of cure, and that it was, therefore, justifiable to undertake such operations when for any reason a complete amputation appeared to be contraindicated.

Professor Ernest Glynn analysed 50 *post-mortems* on patients who had died from cancer of the large intestine in the Royal Infirmary. The rectum was affected in 20, and the pelvic colon in 10 cases. Metastases other than those in the lymphatic glands in the neighbourhood of growth were present in only 19 cases. 30 died from peritonitis, including cellulitis or abscess formation. In 9 there was acute ulceration of the intestine at some distance from the stricture.

Dr. Blair Bell discussed the frequency with which malignant growths of the rectum invaded the ovarian cysts; and contrariwise he had found ovarian carcinoma sometimes invaded the rectum to such an extent as to make it difficult to decide at operation which was the primary growth. Histological examination usually made this question clear.

Mr. Paul, Mr. Newbolt and Mr. R. W. Murray also spoke. Mr. Monsarrat replied.

CENTRAL MIDWIVES BOARD.

Meeting held Thursday, November 20th, 1913.

The President, Sir Francis Champneys, in the Chair.

Correspondence dealt with included a letter from the Norwegian Charge d'Affaires in London, requesting certain particulars regarding the training of midwifery pupils in the United Kingdom, and asking the Board to furnish a memorandum thereon.

A letter was read from one of the Board's examiners calling attention to the ineffective training of a large number of the candidates for the Board's examination owing to the apparent absence of any system of classes at which questions may be asked and explanations given. It was agreed that the substance of the letter be communicated to all the examiners, with the request that they will give the Board their comments upon it, the writer's name being suppressed and "Examiner" being substituted.

Correspondence with Miss E. V. Pocock, a Queen Charlotte's Hospital district midwife, and with Mrs. S. F. Lineham, a pupil of Miss Pocock, with regard to the refusal of the Secretary to accept the schedule tendered by the latter for the examination of October 23rd, and asking that Mrs. Lineham may be admitted to the examination of December 12th, was considered, and a letter was read from the Secretary of Queen Charlotte's Hospital explaining the circumstances attending the taking of her cases by Mrs. Lineham, and the system of training at the Hospital as regards the period during which cases must be taken. The Board decided (*a*) that Mrs. Lineham should be admitted to the examination of December 12th; (*b*) that the Board's circular of April 18th, 1912, should be sent to all training schools, that with each schedule sent to a candidate a form be enclosed on which should be entered the date of each delivery certified, and that such form be signed by both trainer and candidate as correct. It was further resolved that this regulation be communicated to all training schools and approved teachers and midwives under Rule C 1 (2).

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 22nd, 1913.

Epilepsy.

Dr. Maurice de Fleury, Member of the Académie de Médecine, has a conception of his own as to the exciting cause of epileptic seizures, but which seems to be justified by the facts.

At the International Medical Congress held some months ago in London, M. De Fleury read a paper on the subject that received notice at the time. It may be well, however, to recall the principal features of his method of treating that mysterious affection.

Although inclined to believe that in every epileptic there exist cerebral lesions, important in some, constituting the whole malady, hence the little success obtained from every kind of treatment, he was ready to say that in the greatest number the cerebral lesions are but little marked, producing only a predisposition to the attacks. The exciting cause, on the other hand, comes from irritation of the gastro-intestinal apparatus or the toxic residue of a faulty digestion provoking chemical poisoning of the central nervous system.

All neurologists have remarked the frequency of chronic enteritis in patients suffering from epilepsy, preceded by furred tongue, fœtid breath, constipation alternating with diarrhœa charged with mucosities and membranes. According to the doctrine of Herther and Smith, the exciting cause of epileptic fits is in great part due to intestinal putrefaction from excessive indicanuria.

Confirmed in these views, the author proceeded to suppress in the diet of the patients all the richest nitrogenous foods, including milk and eggs, and prescribed largely lacto-ferments recently introduced into therapeutics.

The results were eminently satisfactory. Of 21 cases of pronounced epilepsy, only two remained unaffected by the treatment. The attacks declined rapidly in frequency, and finally ceased altogether. In many cases no returns have been observed for two and three years; they were consequently pronounced cured.

The *régime* is strictly vegetarian, all foods of animal origin are suppressed: milk, eggs, fish, meat. The diet allowed is minutely defined by the author: farinaceous foods, vegetable soups, fresh vegetables, cooked or raw, salad, fruit, honey, jam, sweets. To this is added abundant diuretic drinks as furnished by one ounce of lactose in a quart of water, to be drunk during the day and particularly between meals, and lactic ferments represented by bouillon preferably to compressed tablets, although these latter may be employed with efficacy, and are more easily obtainable. M. de Fleury gives bromides in all the cases to moderate the hypersensitiveness of the motor zone, but in small doses.

The method requires great minuteness in the application of every detail, and also perseverance on the part of the parents and the patient himself. It is only at that price that a cure can be hoped for.

A young man treated by the writer according to the usual methods without any benefit, was placed by his parents in a large and well-appointed institution for the treatment of epilepsy and kindred affections, but with no better results. On the contrary, the fits seemed to have increased in frequency (seven or eight a week) and acuity; moreover, the mind was more or less affected perhaps by bromism. Two months ago he was brough to Dr. de Fleury, who put him at once under the treatment he advocates. The results were not slow to manifest themselves. The seizures ceased, and have not returned up to date. Naturally, the time is too short for drawing a conclusion in this individual case; it is, to say the least, very hopeful.

OXYGEN BY THE RECTUM.

Enemas of oxygen gas have the same indications as hypodermic injections. They may be employed in all cases of mechanical asphyxia and toxic affections met in médical practice.

Thus absorbed, oxygen raises the general condition of the patient and aids in the rapid combustion of the toxins in the intestines. The enemas do not, it is true, possess the rapidity of action of the hypodermic method, but they disinfect the large intestine, an advantage easily recognised.

In entero-colitis, acute or chronic, oxygen gas gives good results; the fœtid odour disappears and the diarrhœa is rapidly attenuated.

The manner of giving the enema is simple. The intestine is first evacuated by a purgative enema, then the gas is injected by means of a soft catheter adjusted to the oxygen bag, and introduced as far as possible into the rectum. The patient is lying on his back, the bag is gently compressed until the colon is filled with the gas, which can be verified by the eye and by palpation. About 2 litres are thus introduced; its absorption is very rapid and completed in about two hours. The enemas may be repeated twice or three times a day.

GERMANY.

Berlin, Nov. 22nd, 1913.

At the Gynæcologische Gesellschaft, Hr. Siegwart showed a ii.-para, æt. 22, who had been delivered spontaneously of twins. Some portions of the placenta were removed manually, after which the uterus was washed out. Soon after this the temperature rose and all the symptoms of pyæmia presented themselves. Streptococci also were found in the blood. The condition underwent many changes, but with every further rise of temperature still more germs were found in the blood in increasing numbers. From the sixteenth day rigors made their appearance, and these increased so much in severity that at last it was decided to open the abdomen. Even before this was decided on a band of thickening had been felt in the right parametrium. On opening the abdomen a large thrombus was found in the right spermatic vein. The vein was followed up to its entrance into the vena cava, and there a ligature was placed around it. From that time there were no more rigors, but only slight rises of temperature due to bed sores. The blood remained free from germs, as it always had been when the temperature was but slightly raised.

Hr. Warneckrose had seen some hundreds of cases in which bacteria were found in the blood with rises of temperature; he considered that in such cases where the numbers of germs were increasing the patient was always lost, but for timely operation.

Hr. Mainzer would avoid touching the interior of the uterus. He would like to learn the views of others on that point.

Hr. Koblank would not have been satisfied with ligature of the vein only, he would have removed it altogether. He had never seen peritonitis follow when that had been done.

Hr. v. Bardeleben had ascertained that the walls of the vein were the best protection against the spread of streptococci; he was quite content with ligatures only.

Hr. Fromme had never made up his mind to ligature a vein; the operation was a serious one, and the results were doubtful. Above all, the indications were not sufficiently precise. There was not sufficient proof in the case before them that the patient would have died without the operation. He held that the result was purely accidental.

Hr. Strassmann was of opinion that it had not been necessary to go into the uterus, that had been a mistake.

Hr. Bumm, the President, said that the bacteriological condition was the decisive factor; the temperature was only of value when considered along with that, and then only when the streptococci were increasing in numbers. Cases that were clinically alike were often quite different bacteriologically.

Hr. Brande showed a uterus with a large perforation opening that had been made with forceps. Not only was the uterus torn, but the vermiform appendix had been seized and torn off and the small intestine injured in four places. In spite of all these injuries, after resection of the appendix, careful suture of the torn bowel and extirpation of the uterus, the patient made an uneventful recovery.

Hr. Sussmann read a paper on what he called the

INCLUSION BLENNORRHŒA OF INFANTS.

He said that in blennorrhœa of infants gonococci were found in not more than half of the cases. Up to the present no uniform ætiology was known in respect of the other half. This lacuna had been filled by the so-called "inclusion blennorrhœa." In the epithelial cells there were included certain bodies that sat caplike on the nucleus of the cell, such as were seen in trachoma. From the staining and the different stages one could see that these bodies grew and that therefore they formed a living virus. Originally they were granules embedded in the protoplasm, which at first were coloured blue, but as the isolated granules grew they became red in colour. These bodies were present also in the secretions of the mother. This inclusion blennorrhœa was present everywhere where there was trachoma, over the whole earth. Half of the blennorrhœas were inclusion blennorrhœas; mixed infections were rare, but they did occur. Experiments had already been made on animals with a positive result. Similar effects had been caused both when the secretion had been taken from the mother and from the urethra of the father. Only the anthropoid apes were susceptible, and where blennorrhœa had been set up there had never been any implication of the cornea. The longer incubation period sufficed to distinguish this form of blennorrhea from the gonococcal. This also explained the occurrence of late attacks. The secretion was not so thick and yellow as in the gonorrhœal form of the disease. It appeared to the speaker that they were on the eve of the discovery of a disease similar to gonorrhœa, and one that had been often mistaken for it.

AUSTRIA.

Vienna, Nov. 22nd, 1913.

The Genesis and Therapeutics of Diabetes Mellitus.

The subject of diabetes mellitus continues to form a focus of very active discussion. At the recent meeting of the K.k. Gesellschaft der Aertzte in Vienna it was again introduced by Dr. W. Falta in a communication on the "theory and treatment" of this interesting clinical condition. He pointed out that there are two queries which specially require to be answered by those engaged in investigation of respiratory metabolism in diabetic patients: (1) Does the consumptive character of grave diabetes depend on an increased heat production, as sometimes is the case in Basedow's disease? To this query Dr. Falta replies in the negative. There is no increase of carbonic acid production or of heat production; but the intake of oxygen is raised in amount on account of the expenditure of substances very rich in oxygen and caloric (sugar and ketone) bodies. We can speak of a consumptive character in those cases only in which the diabetic patient fails to compensate for the waste of caloric in the urine by a corresponding increase in the introduction of nutriment. (2) Can we decide by means of research regarding the respiratory phenomena whether the derangement of metabolism depends on an increased production of sugar, or on a derangement of the combustion of sugar and corresponding assimilation? The former view is supported by Claude Bernard, O. Löwi, O. Porges, and van Noorden, among others; while the latter is favoured by the Naunyn school, and especially by Minkowski. Dr. Falta had, from the results of the researches carried out in association with various co-workers, arrived at the conclusion that the most important lesion in diabetes mellitus is one of the combustion of sugar, in connection with its assimilation; but that there is besides an associated and relatively contingent one present, in the form of a primary over-production of sugar. The assimilative lesion depends on a functional insufficiency of the pancreatic island apparatus: the dissimilatory one on an increased stimulation of certain sympathetic centres, and the functional hyper-activity of the chromaffine tissues thereby elicited. The very low respiratory quotient in grave cases of diabetes mellitus does not contribute to the elucidation of this question, inasmuch as with an enormously increased over-production of sugar in the liver, and copious formation of ketone bodies, the respiratory quotient must be greatly lowered, even when the sugar is consumed exclusively in the rest of the tissues. (Van Noorden.)

But Dr. Falta pointed out that the respiratory quotient indicated a moment in the course of carbohydrate metabolism in which the circulation is overloaded with sugar. In regard to those conditions, the researches which he had himself carried out in connection with Dr. Bernstein gave the following results:—(1) A diet rich in carbohydrates brought about a conspicuous elevation of the respiratory quotient. (2) Intravenous injection of sugar solution likewise raised the respiratory quotient. Generally speaking, then, no sugar need be excreted under these circumstances. (3) The same occurs when the glycogen deposit which is present in the body is mobilised by the administration of adrenalin. The normal organism also possesses the power of rapidly lowering the proportion of sugar in the blood to the normal level of combustion, when the circulation has become flooded by it, and thus preventing any excretory waste of the same. This process of combustion was, apparently, preceded by polymerisation of the sugar—a process to which the author gives the name of glyco-metabolism. He now showed that little or no increase of the respiratory quotient occurs in diabetic patients under those circumstances, and he draws from this fact the conclusion that in the diabetic this faculty of glyco-metabolism has failed more or less completely according to the degree of the functional lesion. This derangement of glyco-metabolism does not completely coincide with that of glyco-genesis, as the former process may remain well in evidence after the latter function has failed. In grave cases, however, both lesions are invariably present.

This view also to some extent gives a clear explanation of the course of events in the carbohydrate cure. According to the researches recently carried out by the author in collaboration with Steinberg, we can utilise in the carbohydrate cure, not only oatmeal, wheatmeal, beanmeal, peameal, bananameal, etc. (van Noorden, L. Blum), but also rice, groats, potatoes and tapioca. In fact, we may combine the various cereals in any way we choose, and with like results. By adoption of a diet consisting exclusively of cereals, the process of glycogen formation is made extremely easy to the organism; as a result of which we find that, in the normal individual, the respiratory quotient begins to show a significant increase only after a whole day's administration; while with a mixed diet, and especially one with a large proportion of meat, in agreement with the results of L. Blum's researches, the formation of glycogen takes place only in very small proportion. In the first case there is very little demand in the function of glyco-metabolism, and an overflow of sugar into the circulation occurs much later. It thus succeeds in filling up again the glycogen depôts more or less completely, and thereby stunting, or at least repressing, the process of formation of ketone bodies.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Medical Guild—Opposition to the Panel.

A large and very successful gathering of medical men, who are not on the panel and are opposed to the principles of service under the Act, was held in the Hall of the Royal College of Physicians, Edinburgh, on November 15th. Dr. John Playfair, President of the Guild, was in the chair, and there were present, in addition to the local members, delegates from London and Manchester. The Medical Guild was founded early in the year, at the time panels were being formed, by the practitioners who were resolved at all costs to remain independent. The business before the meeting was a resolution to the effect that the Guild would federate with all associations holding a similar policy to its own—viz., the maintenance of the honour and freedom of the medical profession, and uncompromising opposition to the method of administration of the medical benefits of the Act. Professor Russell, who proposed this resolution, said that while the members of the Guild had been able to refrain from going on the panel they knew that among those who had been forced by economic causes to serve they had many warm sympathisers. Besides maintaining the honour, they wished to maintain the freedom of the profession, and that included the freedom of the public which under the Act had practically been abolished. He pointed to the alteration which the Act made in the relations of employer and employed of certain classes in the matter of the former caring for the latter in sickness. That was one of the great altruistic developments of our time, and any measure which tended to destroy it was unchristian in its foundation. Under the Act, he asked, were members of friendly societies, colliers, and those under terms of ordinary practice, any better attended than formerly? The very poor dependent on charity for medical attendance were really not benefited—as they would have been under a truly philanthropic Act. The Act was wrong in principle, and an injustice to doctors and patients. He proposed to bring about a closer alliance between the Guild and other bodies holding similar views, and such co-operation made no reflection on other people. Possibly if a Unionist Government came into power it would seriously attempt to remedy the Act in the direction of giving insured persons greater freedom. The resolution was unanimously adopted after speeches by Dr. Jas. Carmichael, Edinburgh; Dr. Monson, London;

Dr. Wheeler Hart, Manchester; and Dr. Green, Wandsworth. Dr. Hart quoted the Bill of Rights to show that the Act had deprived medical men of their rights as citizens. Dr. Green, Wandsworth, said that the report published that at December 31st last there were 2,000 doctors on the London panel was false. He did not believe that the panel membership in London exceeded 1,200, out of 6,300 doctors. The majority were not on the panel, and if 8,000 or 10,000 stood out the Act was bound to fail. Some dissatisfaction was also expressed at the British Medical Association, which was described as antiquated machinery, deserving of being broken up. A very successful dinner of the Guild and its friends was held in the evening.

Revision of Medical Benefit Regulations.

The Scottish Commissioners have issued a memorandum dealing with revision of the benefit in the year beginning January 12th, 1914. Owing to changes of address among the insured it is doubtful whether the register at any time represents the personnel of the insured population with sufficient accuracy to allow of personal allocation within a reasonable time. Under the new regulations the position will be broadly as follows:—Upon permanent or semi-permanent removal insured persons can make a fresh choice of the method by which they will receive medical benefit in their new place of residence. Upon temporary removal all persons may elect to be treated either by a panel doctor or an approved institution, but on returning to their original residence they revert to the arrangement originally made. Persons making their own arrangements will on permanent removal be obliged to make a fresh choice of method; during temporary absences from home they will be able to obtain treatment at their own expense and apply for a contribution from the Committee by whom permission has been granted. Clauses 13 and 14 of the doctors' agreement have been so altered as to obviate the need for appeal to the courts in disputes between doctor and Insurance Committee. They have also been altered to meet the difficulties which are experienced by Insurance Committees in dealing with breaches of the agreement which are either too grave or not sufficiently grave for the remedies provided. Transference of insured persons is inadequate to meet the case of a doctor who leaves his practice without notice or providing a deputy. Even removal from the panel is fruitless in the case of a doctor who has already removed himself from the panel. Gross neglect appears to require action further than transference of the patient or removal of the doctor from the panel, and to meet such cases provision has been made for the recovery of damages under the agreement, and for empowering the committees to refund to the insured person out of the moneys recovered or retained the expenses reasonably and necessarily incurred in obtaining treatment owing to the doctor's neglect.

Glasgow University Assessorship.

Dr. James A. Adams set a difficult task before him when he attempted to oust from his seat in the University Court one of the assessors of the General Council whose term of office had expired; and it is not surprising that he did not succeed. Both of these assessors had a strong hold on the electorate, and it would have required very important differences in policy between them and the new candidate to give the latter a chance. Such differences did not exist. Dr. Adams obtained support from the medical profession, but would have obtained more of such support had he been more prompt and explicit in stating his opposition to the inclusive fee in medicine. When the day for counting the votes came it was found that the votes were:—For Dr. John Hutchison, 3,645; for the Rev. Dr. John Smith, 2,919; and for Dr. Adams, 1,654.

BELFAST.

Queen's University, Belfast.

The late Mr. Wm. Gibson, of Donegall Place, Belfast and Regent Street, London, has left a legacy of £10,000 free of legacy duty, for the purpose of founding certain scholarships in connection with the University to be called "Gibson Scholarships." Mr. Gibson some years ago exhibited his interest in the then newly created University by presenting it with a magnificent and unique silver mace, which has since been used on ceremonial occasions. This valuable legacy is a further proof of Mr. Gibson's interest in the University of the city, of which he was a highly esteemed citizen and successful merchant, and will be the means of helping forward on their educational journey as many as possible of the promising youth of his native province. Of late the authorities of the Queen's University have been gratified to notice how many of the county councils have taken advantage of the excellent clause of the Irish Universities Act, 1908, which empowers them to found scholarships tenable in the University, and the number of such county councils is still growing.

British Medical Association, Ulster Branch.

The autumn meeting of this branch was held in Belfast on Thursday, November 13th, Dr. John Campbell, President, in the chair. The newly elected President, Dr. Lawless, of Armagh, was installed, and a hearty vote of thanks was accorded to the out-going President for his services during his term of office. Dr. Lawless chose for the subject of his inaugural address "The Increase of Lunacy," and dwelt on the various causes for the real and apparent increase of insanity in the three kingdoms. Dr. Warnock, of Donegal, proposed, and Dr. Wm. Calwell, of Belfast, seconded a vote of thanks to Dr. Lawless for his valuable and suggestive address. The vote was passed by acclamation. Professor Lindsay read notes of a case of Landry's paralysis, and in the discussion which followed Dr. Calwell referred to a case in which he had been interested. Dr. W. J. Wilson read a paper on "A Brilliant Green Bile Salt Solid Medium for the Isolation of Bacillus Typhosus." Mr. Howard Stevenson read a communication on "Torsion of the Omentum, with Notes of Two Cases." Mr. T. S. Kirk read a note on "A Common Cause of Movable Right Kidney, and of Stasis in the Ascending Colon." The paper was discussed by Mr. Fullerton and Mr. Crymble. Dr. Coyle gave a demonstration of an Apparatus for the Treatment of Pulmonary Tuberculosis.

Royal Victoria Hospital.

An electro-cardiograph has just been installed in the Royal Victoria Hospital. Dr. McIlwaine, Assistant Physician to the Hospital, gave a demonstration to a large number of members of the profession on the 13th inst. It is proposed also to instal a a new and up-to-date X-ray apparatus in the Royal Victoria Hospital, the existing one now being somewhat out of date. A recent legacy has made it possible to spend a considerable sum of money for this purpose.

Ulster Medical Society.

The Annual Dinner of the above society was held in the Medical Institute on Thursday, 13th inst., Mr. A. B. Mitchell, President, occupying the chair. A very large number of members and visitors were present, as two events of much interest to the profession were to take place. A memorial portrait to the late Dr. Joseph Nelson was unveiled by Mr. J. Walton Browne, D.L. Mr. Browne, in an eloquent speech, referred in feeling terms to the esteem and respect with which the late Dr. Nelson was regarded by everyone who had the pleasure of knowing him. Dr. Nelson, who occupied for many years the post of Ophthalmic Surgeon to the Royal Victoria Hospital and the Belfast Hospital for Sick Children, was a former president of the Society, and took a leading part in building up the Belfast Medical School. The portrait is an excellent one, and will be much admired by Dr. Nelson's old pupils and friends. The honorary Fellowship of the Society was presented to Mr. J. Walton Browne by the President, who referred to the long and faithful services rendered by the former to the Society, the Medical School, and the public of Belfast and the province of Ulster. The toast of "Irish Medicine" was proposed by Professor Lindsay in a speech worthy of the subject. This was responded to by the President of the Royal

College of Physicians, Dr. Fitzgerald, and the President of the Royal College of Surgeons, Mr. Purefoy. Mr. R. J. Johnstone proposed the toast of the visitors, which was responded to by the Recorder of Belfast and Dr. Lawless. The toast of the President was proposed by Sir Thomas Myles, of Dublin, and responded to by the President, who proposed the toast of the Secretary, Mr. S. T. Irwin. The function was one of the most successful in the annals of the Ulster Medical Society.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

SMALLPOX AND VACCINATION.

To the Editor of The Medical Press and Circular.

Sir,—To one who takes no orthodox view about vaccination the review of Dr. Hanna's book in your issue of the 19th inst. is distinctly encouraging. I am old enough to remember a considerable change of public opinion on this question, and you, Sir, will no doubt also recollect that the late Mr. Ernest Hart in the early days was very outspoken about the anti-vaccinist class, whom he stigmatised as guilty of "crimes against humanity," and whom he would have punished as malefactors. By the time the Royal Commission had begun to get to work Mr. Hart referred to the "few noisy and uninformed persons" who "wickedly" and "senselessly" preached the doctrine of anti-vaccination, but that "such learned gentlemen as Mr. Hopwood, Q.C., M.P., were, of course, fully entitled to hold and preach their political doctrines of non-compulsion as a theoretic creed." Later still, at the time of the Gloucester epidemic, anti-vaccinators were no longer "criminal," or "wicked," but "ignorant fanatics," and now I notice your reviewer only uses the rather harmless term "faddists," but with "wiles" of "much skill and ingenuity," which is rather complimentary, at any rate, to their intelligence, and he thinks that really a good deal of the blame ought to be laid at the door of the medical profession, who obstinately decline to educate the public, and with this we shall all cordially agree.

But when your reviewer, in a much limited space, commences to deal with figures, does he not rather overestimate the small-pox mortality of the 18th century? It may well be that high figures may be on record for hospitals, but 25 to 40 per cent., I should say, were exceptional rather than average numbers. It is true that in recent years there has been a marked reduction, but a much more likely explanation is that this has been occasioned by improved sanitary measures and by the more rational methods of nursing of which Florence Nightingale was the pioneer. I say this because Dr. Hanna's fatality for the last ten years at Liverpool is 7.6 per cent. (1,163 cases and 88 deaths), whereas I find that the statistics for Leicester are still lower—viz., in the epidemic of 1892-1894, just 5.9 per cent. (355 cases and 21 deaths), while the proportion of those attacked by small-pox who were vaccinated in Liverpool and Leicester respectively was 81 per cent., and 55.6 per cent., thus indicating that Liverpool was better "protected." Does not this tend to show that some factor or factors other than vaccination have been at work? although, of course, I fully admit that your reviewer, in trying to compress the whole case for vaccination in a few lines, did himself very inadequate justice for the elucidation of so difficult a problem.

I am, Sir, yours truly,
W. Scott Tebb, M.D.Cantab.

London.
November 21st, 1913.

POSTERIOR RHINOSCOPY.

To the Editor of The Medical Press and Circular.

Sir,—I read with interest Dr. William Lloyd's "Note on a new Posterior Rhinoscope," published in yesterday's Medical Press and Circular, though I do not agree with the title "new." If Dr. William Lloyd will refer to Volume 11, "Selected Monographs," published by the New Sydenham Society in 1861, he will find (pages 26 and 27) the description and illustration of a post-rhinoscope designed by Czermak, which to all intents and purposes is identical with that of Dr. Lloyd. Further the method of illumination by means of a Bruning's handle is not new, as it has been used and described by Von Gyergyai in 1910 and 1913 (for full references see *Deutsch. Medizin. Wochenschrift*, No. 25, 1913), and was demonstrated by him at the recent International Congress of Medicine. The method of retracting the palate by means of rubber tubing to permit of the introduction of the instrument and examination of the post-nasal space seems to me to be an unnecessarily severe and complicated procedure for routine examination purposes, especially when an easy, accurate and painless examination can be made with the naso-pharyngoscope (Holme's method, see the writer's paper on "The Direct Examination of the Eustachian Tubes and Nasopharynx," *Journal of Laryngology*, November, 1913).

Dr. Joseph C. Beck, of Chicago, has described a new method for the removal of adenoids under direct inspection, in which the palate is retracted by means of a rubber catheter passd through the nose (*Annals of Otology*, Vol. 22, June, 1913), but this method of palate retraction is not new, and has long been used by surgeons when operating upon the post-nasal space.

I am, Sir, yours truly,
J. Walker Wood.

30 Canfield Gardens, Hampstead.

LONDON MEDICAL COMMITTEE.

To the Editor of The Medical Press and Circular.

Sir,—Will you kindly insert the following report of the meeting of the London Medical Committee of November 17th in your paper, and oblige?

I am, Sir, yours truly,
E. Arthur Dorrell.

45 Welbeck Street, W.
November 18th, 1913.

At a meeting of the London Medical Committee (non-panel) on November 17th, notice was received of a non-panel association for Deptford. Dr. Greene, who had just returned from a meeting of non-panel men in Edinburgh, reported that over 40 per cent. of the doctors in Edinburgh had not joined the panel, and that 400 in Glasgow had not gone on.

With reference to a recent attempt to work a scheme to pass all persons suffering from tuberculosis through the voluntary hospitals, to be there examined and allocated to dispensaries or sanatoria, the following resolutions were passed by the Committee:—

(1) That the London Medical Committee, while recognising that there is a place for the co-operation of sanatoria and hospitals in the treatment of tuberculosis, is strongly of opinion that the domiciliary treatment of tuberculous persons, as well as that carried out in local dispensaries, ought to be entrusted, to the fullest possible extent, to practitioners engaged in general practice.

(2) That this Committee is of opinion that the voluntary hospitals to which medical schools are attached should have the opportunity of having all the clinical material they need for teaching purposes.

(3) That in the opinion of this Committee the acceptance of payment out of public funds for special treatment in a voluntary hospital is contrary to the interests of the public and the profession.

(4) That the Council of the British Medical Association be requested to forward forthwith the subjoined resolutions to the various Divisions for the earliest possible expression of opinion by them.

On the question of the unallocated medical benefit insurance funds the Committee passed the following resolution:—"That the Committee suggests to the Non-panel Committee of the Council of the British Medical Association that they should endeavour to obtain an injunction against the London Insurance Committee distributing the medical benefit of the unallocated insured persons among the practitioners on the panel."

THE PANEL SYSTEM AND ITS ANOMALIES.

To the Editor of The Medical Press and Circular

Sir,—Only a month ago I was grumbling at your statement that medical men received a windfall from the Insurance Act. I now congratulate you that you have adopted a somewhat different tone. In the article headed "What of Wisbech?" you say the Chancellor "left the profession for the time being more or less discomfited," and remark that "it is hardly likely that any large section of educated Englishmen will allow themselves to be exploited." This is only what one would expect from an independent journal like the Medical Press, not in fear of resignations nor of what a German doctor calls the Judas-like defection of colleagues and neighbours. Even now, if I may say so, you only nibble at the "mint and cumin," and neglect the serious and most substantial matters. Herbalists, faith healers, Christian Scientists, etc., do the profession comparatively but little damage, although it may be annoying and derogatory to find their certificates accepted (if they are) in cases of illness. But the great loss to the medical profession is that panel doctors have to give certificates free of charge to all approved societies. You have not a word of criticism or guidance as to the draft agreement, the second paragraph of which makes it an offence to receive any remuneration for extra attendance.

I might mention many cases where attendance is given not for health but for appearance, but I will mention a case of treatment. A young fellow, whose father makes between three and four thousand a year, has to be insured because he only earns about £2 a week in an office. He got pneumonia, and the father came to me and said, "See here, doctor, I wish my boy to get the best attention. I can't expect you to visit him three or four times a day for the panel pay, but pay as many visits as you think necessary and charge to me." Was I doing a dishonourable thing in giving my best attention at the crisis and charging the father for it? I do not think so. But under the draft agreement I could not do so. Is it not possible for you to get from some of those who have had large panel practices a statement of the amount of work they have had to do and the remuneration for such services? You have ridiculed the threepenny doctor, but from my experience, taking what I have received in payment and the work done, my remuneration has not much exceeded that of the threepenny doctor, and there is this to be said for him—he keeps his liberty. Mr. Churchill has made a statement of the number of visits and attendances made by doctors, but as we all know that as the cards giving such statistics are still in our possession the statement is a mere guess. This is dishonourable.

I am, Sir, yours truly,
London, S.W. An Old Radical.
November 22nd, 1913.

THE FUTURE OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of The Medical Press and Circular.

Sir,—The deep interest which you take in the welfare of every practitioner encourages me to ask you to take up especially the question of the "Future of the Royal College of Surgeons" of England.

The time has now come when the matter must be faced resolutely and definitely as to what is best to be done to bring the administration of the College up to modern requirements.

We all recognise to-day that the Reformation was a sad thing in the Church, and that the Revolution was an evil remedy in the history of France, but we must all of us have come to the conclusion that both these remedies were forced upon unwilling people because constitutional remedies were refused them.

For nearly twenty years the Members of the College of Surgeons have mildly, politely and constitutionally pointed out every year to the Council that it was only fair and right that they should have a voice in the Corporation of which they constitute the greater part in numbers, and provide the greater part in income. Secure in the safety of a Charter, the Council have entirely ignored these polite and just requests.

There remains, therefore, now nothing but stronger remedies, and since at the annual meeting last week almost the whole business consisted in Fellows and Members uniting unanimously in condemning the administration, the finances, the lack of initiative, and the neglect of the welfare of the members of the Corporation by the Council, it is time that steps were taken to put an end to such anomaly.

Corporations which have outgrown their Charters must have new ones; a living body must not have its growth hindered by the dead hand of bygone years. The Charters of the past suited the past, but are unsuited to the present, and therefore I venture to ask you to find space in which I may appeal to every Fellow and Member of the Royal College of Surgeons to unite in appealing to the Privy Council for an alteration of the Charter of the Royal College of Surgeons, so that some representation and some rights of administration should be given to the seventeen thousand M.R.C.S.'s, instead of being, as at present, restricted to the less than two thousand F.R.C.S.'s.

I am, Sir, yours truly,
Josiah Oldfield, D.C.L.Oxon, M.R.C.S.
1 Mitre Court Buildings, Temple, E.C.
November 24th, 1913.

SPECIAL REPORTS.

ROYAL COMMISSION ON VENEREAL DISEASES.

At the third meeting of the Royal Commission on Venereal Diseases, held on November 13th, Dr. R. W. Johnstone, Medical Inspector of the Local Government Board, gave evidence which followed generally the lines of the report on venereal diseases written by him and issued by the Local Government Board in August last.

He found much difficulty in arriving at a conclusion on the question of the prevalence of the diseases in the population. The figures given by the Registrar-General could not be relied upon for information of the number of deaths from venereal disease, and this was inevitable owing to the reluctance of medical practitioners to certify deaths as due to this cause. The death-rates from a number of diseases known to be caused by syphilis, instead of showing a decrease, as would be expected if syphilis were diminishing, were stationary or tended to increase. The figures relating to venereal diseases in the Army showed remarkable decreases, but were subject to some qualifications, and in any case could hardly be taken as an exact reflection of the state of the civil population. Men in the Army, through the instruction given by their officers, were much better educated with regard to these diseases than the ordinary civilian.

For the purpose of obtaining trustworthy statistics of the prevalence of these diseases, he thought that certification of deaths should be confidential, but that this change should be made with regard to all diseases and not only venereal diseases. He was of opinion that information of value might be gained if a special return were obtained from general hospitals.

As to notification, he said that he was opposed to the introduction of any compulsory system. He understood that there was a possibility of a system accompanied by the names of patients being put in force in one of the Scandinavian countries; but treatment by quacks did not flourish there to the same extent as in England, and he thought that there was not the same danger of notification leading to the concealment of the disease. From the point of view of the public health of the country in relation to venereal diseases, the objects of primary importance to be secured were the prompt recognition of the diseases and their early treatment. To this end he advocated that facilities for laboratory diagnosis should be provided, and that the available hospital accommodation, which at the present time was entirely inadequate, should be supplemented. He was not in favour of the erection of additional special hospitals to deal with these diseases, as he was anxious to avoid anything which would tend to have a deterrent effect. He was of opinion that the more the general hospitals could be used the more freely patients would present themselves for treatment.

Dr. Johnstone pleaded for greater frankness on the part of the public with regard to these diseases. If the public were properly educated in the matter and the necessary facilities for treatment were provided, there was now an opportunity of reducing the diseases to very small dimensions.

On November 17th statistical evidence as to the prevalence of venereal diseases in the Army was given by Lieut.-Col. Scott, Deputy Assistant Director-General of the Army Medical Department. The figures furnished by Col. Scott were for the period from 1888 to 1912, and related to the rejections of recruits on account of venereal disease, the admissions to hospital, the numbers constantly sick, and the numbers invalided from the Service from this cause. Under all these heads remarkable reductions were shown. The rejections on recruiting had fallen from .63 per cent. of the candidates in 1890 to .14 per cent. of those presenting themselves in 1912. The admissions to hospital in the United Kingdom, which stood at 224.5 per 1,000 of the forces in 1888, had dropped to 56.5 in 1912. There were corresponding falls in the figures of constantly sick and invalids. In the case of India the reductions had been still more marked.

Col. Scott showed that certain qualifications have to be borne in mind in comparing the earlier with the later years, but he was satisfied that real progress had been made and that the figures did indicate a large measure of success in dealing with the diseases in the Army. He was not prepared to say whether the figures indicated a corresponding improvement in the civil population.

MEDICAL NEWS IN BRIEF.

Asylum Medical Officers.

A conference of assistant medical officers of public asylums, held at Birmingham last week, decided to form an association for the protection of the interests of the profession. At the present time, it was stated, assistant medical officers were subjected to many disabilities. Asylums could not get assistant medical officers because young medical practitioners recognised that if they went into asylum service they might not be allowed to get married, or if they did so they might be required to live apart from their wives.

Further, it was found that after several years' experience as assistant medical officer in a public asylum the salary was no more than that of a man who had only just qualified. It was not unusual, it was stated, for an assistant desiring to attend a meeting to be refused permission by his superintendent. Circulars inviting attendance at the conference were sent to assistants at 35 Midland asylums, and all but six sent representatives or letters of sympathy with the objects of the meeting.

Treatment by Christian Science.

An inquest was held at Chelsea on Monday last on the body of Mary Ann Thrower, 66, of Basil Mansions, Basil Street, Chelsea.

Captain Braithwaite, of Basil Mansions, said the woman had been a trusted servant of the family for over forty years. She was a Christian Scientist, and had been in the habit of visiting a Mrs. Rennie, also a Christian Scientist. On Thursday afternoon Thrower fainted, and the witness telephoned for Dr. Furber, the family medical attendant. When Thrower recovered consciousness she asked for Mrs. Rennie to be called, and the latter arrived before the doctor. The witness asked Mrs. Rennie to persuade Thrower to see a doctor, and Mrs. Rennie agreed that it was the best course to take. Dr. Furber subsequently prescribed for the woman, who took the medicine. On Friday morning Dr. Furber was again sent for, but the woman died.

Dr. Furber, of Welbeck Street, W., said the woman appeared to be suffering from internal hæmorrhage, set up by an ulcer in the stomach.

Marie Rennie, wife of an engineer, of Elveston Place, Kensington, said she was a Christian Scientist and professed to heal sickness and disease. She had known Thrower about three years, the latter having called at an office in Alfred Place, which was used by the witness and other Christian Scientists for consultations. Thrower complained of pains from indigestion, and came at long intervals for treatment. She always said she felt better after the treatment, which consisted solely of prayer. If the woman had got worse the witness would not have stood in the way of her seeing a doctor.

Dr. Spilsbury, of St. Mary's Hospital, said the cause of death was hæmorrhage, set up by a large ulcer in the stomach. If the ulcer had been treated by medicine and dieting in its earlier stages its progress might have been arrested.

The jury returned a verdict in accordance with the medical evidence, adding that death was accelerated by the want of proper medical attendance. They also expressed the opinion that such persons as Mrs. Rennie should not be allowed to practise as professional healers.

The Coroner said he hoped it would act as a warning to such persons.

Control of Massage Houses.

It is reported that the London County Council will seek powers in the next Session of Parliament enabling them to require the registration of premises used as nursing homes, or for massage, manicure, electrical treatment, and similar purposes. The Bill is apparently to be of very wide scope, and a register is to be kept of all except specially exempted institutions. One of the provisions is thus outlined:—

"It shall be an offence for any person or company knowingly to advertise, or print, or publish an advertisement of any owner or occupier who has been struck off the register."

It is also to be provided that:—

"In any case in which a business not included in paragraph (i.) above is advertised, and the registration authority has reason to believe that the title of such business has been adopted as a cloak to the carrying on of a disorderly house, officers appointed by the registration authority shall have a special right of entry, subject to such regulations as may be made by the registration authority, into the premises concerned, and the registration authority shall be empowered to institute legal proceedings, if necessary, as a result of the inspection of the premises."

The charge for registration of premises is not to exceed two guineas. The penalties for breach of the law range up to £50, with a daily penalty of £20, and imprisonment after the first conviction.

University of London.

The following have passed the third (M.B., B.S.) examination for medical degrees for internal and external students:—

Honours.—H. J. O. Ewing (*a*, *e*, University Medal), H. L. H. Greer (*e*), A. E. Hallinan (*b*), L. M. Ladell (*a*), A. C. Palmer (*e*), C. E. Thornton (*a*). (*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*e*) Distinguished in Midwifery and Diseases of Women.

Pass.—J. Appleyard, C. H. Attenborough, Margaret M. Basden, A. C. L. O'S. Bilderbeck, G. F. Bradley, A. J. Clarke, R. J. Clausen, F. W. T. Clemens, J. A. Cowan, J. M. Curé, J. P. Davies, R. D. Davy, S. F. Dudley, W. H. Eggar, Pattie R. Elliott, A. S. Erulkar, D. M. Gibson, C. E. A. Goddard, C. F. Hacker, C. C. Harrison, G. M. Heiron, P. H. Henson, M. Hocken, T. H. Holroyd, J. M. Joly, W. H. Jones, T. P. Kilner, W. Leslie, Muriel A. Lloyd, Margaret J. McEnery, G. Matthews, H. B. Parker, Hilda M. Pollard, W. J. A. Quine, H. M. Rashbrook, A. E. Roberts, A. D. Rope, D. Ross, A. L. Shearwood, H. Smith, E. N. Snowden, E. S. Sowerby, J. Vaughan-James, H. B. Walker, E. W. Whiting, G. Whittington.

Dr. J. Edward Squire, C.B., F.R.C.P., who for the last thirty years has been associated with the Mount Vernon Hospital as an Assistant Physician and a Physician, has been elected a Consulting Physician to the Hospital.

Summary of Recent Medical Literature English and Foreign.

Specially compiled for The Medical Press and Circular.

Cerebral Syphilis.—Henderson (*Amer. Journ. of Insanity*, October, 1913) records the result of a clinical analysis of twenty-six cases of cerebral syphilis, seven of which came to *post-mortem* examination. He comes to the conclusion that syphilis plays an important part in the production of mental disease, more so even than has heretofore been suspected, though trauma, alcoholism, and physical and mental strain are important contributory factors. From an anatomical point of view, three main types of the disease can be differentiated—meningitis, endarteritis and gumma—but clinically this differentiation is not always possible, and is not of great practical value. The majority of cases of cerebral syphilis develop within the first three years after primary infection, and cases occurring ten years after infection are rare. This is in striking contrast with cases of locomotor ataxia, in which a later development is the rule. With regard to the physical signs, Henderson lays most stress on the Argyll-Robertson phenomenon, which he states is rarely present in cerebral syphilis. Other important features are an acute onset with headache, dizziness and vomiting, cranial nerve palsies, convulsions without loss of consciousness, but followed by permanent focal symptoms, the maintenance of intactness of speech and writing, and the absence of facial tremor. Six of the patients whose cases are recorded presented symptoms of pseudo-bulbar paralysis. Recent statistics confirm the opinion that the prognosis in cerebral syphilis, as compared with other organic affections of the nervous system, is relatively good; the most favourable are those which develop soon after the primary infection, and those of the meningitic or gummatous type. Mercury, given systematically, remains the most valuable drug in the treatment of the disease, but the best results known are obtained by combining the mercurial with the salvarsan treatment. K.

The Heart in Syphilis.—Brooks (*Amer. Journ of the Med. Sciences*, October, 1913) finds that serious involvement of the heart is frequent in syphilis. The epicardium, the endocardium, or the myocardium, or all together may be so diseased. The cardiac involvement may develop early in the infection, though its symptoms may not be apparent till late. The signs and symptoms when they appear are those of cardiac disorder, and there is little or nothing except the history, the general aspect of the patient, and the Wassermann reaction to indicate the true ætiology of the condition. Treatment should first be directed towards the improvement of the circulatory trouble; and, secondarily, though most productive and important of all, it must be specific. As a rule, good results follow appropriate antisyphilitic treatment. In each case this treatment should be individual, but the combination of mercury and salvarsan seems, as a rule, to give the best results. Sometimes one, and sometimes the other alone appears to give better results. Whatever treatment is adopted it should be continued till a permanent negative Wassermann reaction is obtained. Subsequent to this the management of the case should be along circulatory and not luetic lines. K.

Salvarsan in Syphilis.—Pusey (*Amer. Journ. of the Med. Sciences*, October, 1913), from an examination of our present knowledge in regard to syphilis and its treatment, comes to the conclusion that the real danger in the use of salvarsan is remote, though when it occurs it is serious. He believes that we have no good reason for believing that the use of this drug will lessen the occurrence of parasyphilitic nervous lesions, and thinks that there is some ground for the fear that it may predispose to them, except in those cases in which it cures the disease. There is no doubt that it is a powerful symptomatic remedy, and there is much evidence for thinking that where vigorous treatment is begun before the disease has generalised, the syphilis may be aborted. When the drug is used in the secondary stage, and in its result falls short of absolute cure, it is probable that its use may do positive harm to the patient. Owing to the destruction of the spirochætes, except those walled off in inaccessible parts, the body is not stimulated by the general infection to the formation of those antisubstances which are its natural defence, and so builds up little or no resistance to the subsequent invasion when the shut-off organisms again are set free. K.

Induction and Augmentation of Labour Pains.—Welz (*Amer. Jl. Obs.*, lxviii., 1) studies the experiments reported by others, and reports six cases of pregnant women whom he injected with fœtal serum in quantities varying from 18 cc. to 28 c.c. Four of the cases responded to the injection, and the birth of the child followed. Three of these cases were well developed, and one was overdue. The fourth case was in the thirty-fourth week of pregnancy, and had pre-eclamptic toxæmia. He says that the uterine fibres exhibit a definite rise of tone in response to extreme dilutions of antigen. The *ante partum* contractions of the uterus are probably due to a minor anaphylactic shock of lesser degree than that present in true labour, and also in false labour the process has not been severe enough to cause labour to proceed to its termination. Missed labour and overtime pregnancy are possibly due to an insufficient flow of birth substances into the maternal organism. In syphilis the inflammatory disturbances in the placenta allow increased amounts of birth substances to enter the maternal circulation, thus causing early birth, miscarriage and abortion. Thirty cases are reported in which pituitrin was injected to hasten the termination of labour. The average time from the injection to the end of the second stage was 4.3 hours. The average time of labour was 15.2 hours. Most of these cases responded well to i.c.c. Except in three cases the response was very evident in the longer duration of contractions, shorter intervals, and greater strength. In a few there seemed to be a tonic contraction with severer clonic contractions at regular intervals. The writer believes that parturition is caused by an anaphylactic action of proteid from the fœtus to the mother. The danger of anaphylactic shock must be kept in mind. F.

Pituitary Extract in Uterine Inertia.—Edgar (*Amer. Jnl. Obs.*, lxviii., 1) records seventy cases, 39 in the first and second stages, 19 immediately after the third stage, 6 in Cæsarean section, and 6 for induction of abortion. Vaporoles or ampoules of the drug should be used to obtain trustworthy results. For decided action 0.4 gram is required as an initial dose; repetition may be called for, as the action of the drug disappeared in about 25 minutes. If no response is secured after a second dose, the drug may be abandoned. When full or repeated doses have been given and too great resistance to delivery exists, the contractions approach to the continuous in character. In the first stage before the cervix is shortened, full doses are equivalent to ergot, and should not be used, as they may produce premature separation of the placenta, fatal compression of the fœtus, and even uterine rupture. Uterine inertia at this stage should not be treated by pituitary extract. In cases with a dilated or readily dilated cervix with inertia and not too much resistance to be overcome, the extract renders valuable aid. The observations show that the drug acts best at full term in the second stage, and if administered shortly after spontaneous or artificial rupture of the membranes. Its action was least marked when used for excessive bleeding following the third stage, and in 19 cases was disappointing. In Cæsarean section the extract appears to act quicker than ergot, but the action does not last so long. Labour has failed to be induced by the action of the drug alone. In abortions the action was disappointing. The action of the drug is uncertain and cannot be predicted from the amount of dose, the character of the inertia, or the resistance to be overcome. The drug should never be employed for inertia in any stage of labour, unless anæsthesia is at hand, and preparations complete for immediate operative delivery, to avoid uterine rupture. F.

The Operative Treatment of Inoperable Cancer. Rowntree (*Brit. Med. Journ.*, Sept. 27, 1913) pleads for the operative treatment by removal of a cancer even when there is no hope of eradicating the disease by this procedure. He points out that, for instance, the life history of a case of cancer in the tongue resolves itself into the history of the tongue itself—a history of ever-increasing pain and discomfort, and the offensive ulcer which it is impossible to keep clean. The patient, worn out by pain, loss of sleep and septic poisoning, falls an easy victim to broncho-pneumonia, gangrene of the lung, or some similar affection. In cancers of the tongue, breast, and uterus, the patient does not die from cancer, but from sepsis and its concomitants. The writer considers that few patients should be allowed to die of the primary growth alone; the number of secondary deposits ought to be in direct proportion to the excellence of our treatment, as they certainly are to the duration of the disease. In this connection the writer collects some figures. The average length of course of cancer of the tongue, untreated by operation, is fourteen months. The number of these cases in which metastases are found in internal organs is 6 per cent. Similarly the average duration of cancer of the cervix uteri is twenty-one months, and dissemination 15 to 20 per cent. Of the lip, twenty-four months and distant secondary deposits 25 per cent., while in cancer of the breast, with a total average life of three and a half years, the number of deposits is no less than 50 to 60 per cent. From these figures and facts the writer deduces that a patient suffering from incurable cancer dies too soon by several months, and that life can and should be prolonged by palliative operations on the primary growth. Prolongation of life, which in breast cancer averages two and a half years, is not the only advantage gained, but increased comfort, or rather some diminution of the dreadful misery of inoperable cancer, should be aimed at. In connection with the question of technique, that which is adapted for the radical operation is unsuitable for a palliative one. It suffices to remove the breast with all obvious growth. The wound is then covered with thick healthy flaps, which will not be penetrated easily by any growth that may have been left behind in the chest wall. In amputating a leg for inoperable sarcoma, the line of section should be just about the growth, not necessarily at the hip joint. In the tongue a simple Whitehead operation, with its low mortality, is all that is indicated when radical measures are not possible. One's aim is to remove the maximum of disease with the minimum disturbance of healthy tissue. Two dangers to guard against are sepsis and infection of the wound with cancer cells, both of which may occur in so-called operable cases. S.

Three Successful Operations for Perforated Typhoid Ulcer.—Mitchell (*Brit. Med. Journ.*, September 20th, 1913), operated on the cases 5, 4½ and 14 hours after perforation respectively, the patients being in the 43rd, 21st and 29th day of the disease. They all recovered. The operations were performed as quickly as possible, through a median incision below the umbilicus. The writer concludes that the quickest way to find the perforation is to go straight for the ileo-cæcal valve and trace the ileum upwards. It will rarely be necessary to handle more than two or three feet of bowel. All sutures should be of catgut, as silk or linen is sure to become infected and give rise to troublesome sinuses. The catgut the writer uses is prepared by boiling in absolute alcohol for thirty minutes, and stored in tincture of iodine one part, proof spirit ten parts. These patients bear the Fowler position and continuous rectal saline well. Coliuria being a very likely complication, it appears wise to put these patients at once on alkaline treatment. The writer uses 10 to 20 grains of sodium citrate every four hours. S.

Hæmic Infections of the Urinary Tract.—Kidd (*Practitioner*, November, 1913) states that pyuria, if accompanied by fever, means that pus is coming from either the deep urethra or the kidney. In males the two-glass test is necessary to distinguish between these two origins, but in females febrile pyuria means affection of one or both kidneys. Spontaneous natural cure is the rule rather than the exception in hæmic infections of the urinary tract. The kidneys may recover long before the bladder. This the writer has proved in six of the cases (18 per cent.). For instance, in one woman pus and streptococci were found in the urine drawn off from both kidneys. A week later, the fever having subsided, the bladder urine still contained blood and streptococci, but urine drawn from each kidney was clear and sterile. During the ensuing fortnight, two bladder instillations of silver nitrate (5 gr. to the ounce of water) sufficed to bring about a complete cure. Lavage of the renal pelvis cures most, if not all, of the very chronic cases. To illustrate how simple this treatment is, the writer states that he has washed out the kidneys of five different women in the course of half an hour in his cystoscopic room in the London Hospital. The author cites cases to show that pyogenic bacteria may enter the urinary tract through the blood stream, by way of the prostate, and not by the kidney. Acute hæmic urinary infections are very seldom fatal, and it is extraordinary how ill a patient may be, and yet how quickly he can recover. Nephrectomy is only necessary for a few hyper-acute cases and a few unilateral chronic cases, which resist all the treatment for eighteen months or more. In the writer's experience, the results of vaccine treatment are not satisfactory. A patient suddenly seized with pyuria and fever should be put to bed, and kept there for at least a week or ten days after the fever has disappeared. Over-exertion is the great predisposing cause of infection and re-infection. Diuresis and diaphoresis are promoted in the usual way. Potassium citrate is exhibited in large doses for two or three days till the fever shows signs of abating, when a change is made to urotropin, 5 to 10 grain doses four times a day. A catheter specimen is obtained for bacteriological investigation. Skiagrams should be taken to exclude stone, and collargograms if necessary. At the end of another week the ureters should again be catheterised, and if the kidneys have recovered, a few instillations of silver nitrate into the bladder will cure the case. If the kidney is still infected, either the catheter should be left *in situ* to drain the pelvis and enable it to be washed out twice a day for a few days, or the ureters should be catheterised every fourth or fifth day, and the pelvis washed out with 5 c.c. of 5 per cent. collargol. In chronic cases general treatment is of the utmost importance. Urotropin should be prescribed in 5-grain tabloids, one or two taken in plenty of water four times a day after meals, without intermission for at least six months. It is no use prescribing urotropin in fluid mixtures, as it decomposes almost at once. S.

Royal College of Surgeons of England.

It is announced that the Bradshaw Lecture will be delivered in the Theatre of the College by G. H. Makins, Esq., C.B., F.R.C.S., on Friday, December 5th, at 5 p.m. precisely. The subject of the lecture will be "Gunshot Wounds." Fellows and Members of the College are invited to attend. Students and others who are not Fellows or Members of the College will be admitted on presentation of their private visiting card.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

P. R. (Suffolk).—Our correspondent will find every information respecting the climate, clothing, etc., for the district he mentions in Dr. G. Montagu Harston's book on "Care and Treatment of European Children in the Tropics." (Bailliere, Tindall and Cox.)

DR. A. M. B. (Herts).—The question of the amount of injury inflicted by an electrical current depends largely upon whether at the time of contact the patient's clothes and boots are dry or not, also whether he is standing on damp earth. The delicate or moist skin of a clerk's hand is a better conductor than the harder and drier palm of a workman.

WIRELESS.

A CORRESPONDENT (A. D.) sends us the following:—"My dear Sir," said the Doctor, "You suffer, unfortunately, from a complication of diseases, each sufficient to kill you, as very few important organs have escaped, so that it is quite impossible to say which of your complaints will be the direct cause of your death? However, if you will be kind enough to direct that I shall make your autopsy, I shall be happy to send you result by wireless should you be able to leave your future address."

M.B.EDIN. (London, S.E.).—The Milne treatment of scarlet fever consists briefly of the brushing of the throat every second hour for the first 24 or thereabouts, according to results, with 1 in 10 carbolic oil, and the inunction of the body all over, hairy parts and all, with undiluted eucalyptus oil, twice daily for the first four, and once a day for the next six days, making 14 inunctions in all. After this period it is claimed by Dr. Milne that the patient is free from infection.

Meetings of the Societies, Lectures, &c.

FRIDAY, NOVEMBER 28TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Dr. F. G Crookshank, Mr. Lionel E. Norbury, Mr. Philip Turner, Dr. H. Tipping, Dr. C. E. Zundel, Mr. W. J. Midelton, Dr. F. J. Poynton, Dr. Frederick Langmead, Dr. F. G., Crookshank, and other cases.

ROYAL SOCIETY OF MEDICINE (SECTION OF EPIDEMIOLOGY AND STATE MEDICINE) (1 Wimpole Street, W.).—8.30 p.m.: Dr. E. C. Snow and Dr. Hilda Clark.

MONDAY, DECEMBER 1ST.

MEDICAL SOCIETY OF LONDON.—8 p.m.: Clinical Evening.

TUESDAY, DECEMBER 2ND.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND, 11 Chandos Street, Cavendish Square, W.—1.45 p.m.: Council Meeting. 3 p.m.: General Meeting. Papers:—Dr. E. Faulks. Adjourned discussion on Dr. Getting's paper on Asylum Dysentery.

THURSDAY, NOVEMBER 27TH.

HARVEIAN SOCIETY OF LONDON.—8.30 p.m.: Discussion on the Registration of Venereal Diseases. The following have promised to take part: Dr. Stevenson, Dr. Blacker, Dr. Cautley, Dr. Maude, and Dr. Dudfield.

Appointments.

BRIDGE, J. C., F.R.C.S.Edin., D.P.H.Camb., Medical Inspector of Factories.

COOK, JOSEPH BASIL, M.D.Vict., D.P.H., Medical Superintendent of the Brentford Union Infirmary, Isleworth.

DWYER, JAMES J., L.R.C.P. and S.Irel., Clinical Assistant to the Chelsea Hospital for Women.

HARWOOD - HARDMAN, FREDERICK, M.D.Edin., Honorary Radiologist to the Princess Alice Memorial Hospital, Eastbourne.

LEY, GORDON, F.R.C.S.Eng., Pathologist to the Chelsea Hospital for Women.

LONG, D. SANDERSON, M.D.Cantab., Honorary Medical Officer to the York Dispensary.

PATRICK, JOHN, M.B., B.Ch., R.U.I., Resident Medical Superintendent of Tyrone and Fermanagh Asylum.

ROSS, WILLIAM, F.R.C.S.Edin., Examining Surgeon to the Collieries at Ebbw Vale, Monmouth

Vacancies.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Kirkliston (Linlithgow), Milltown (Co. Kerry).

General Infirmary, Macclesfield.—House Surgeon. Salary £125 per annum, with board and residence. Applications to the Chairman, House Committee.

Seamen's Hospital Society, Greenwich, S.E.—Medical Superintendent. Salary £150 per annum, with board, residence, and washing. Applications to P. Michelli, Secretary.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £180 per annum, with board, lodging, and washing. Applications to Dr. G. Hamilton Grills, Medical Superintendent.

St. Bartholomew's Hospital, Rochester, Kent.—Resident House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to Charles Speyer, Secretary.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—A Casualty Medical Officer. Salary £200 per annum, with luncheon. Applications to the Secreary at the Hospital. (See advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—A House Surgeon. Salary £30, washing allowance £2 10s., and board and residence in the Hospital. Applications to the Secretary. (See advt.)

Births.

KAY.—On November 20th, at 3 Pembroke Gardens, Kensington, the wife of Dr. Charles Wallace Kay, of Lymington, Hants, of a daughter.

LEGGE.—On November 22nd, at 5 Cannon Place, Hampstead, the wife of Thomas M. Legge, M.D., of a son.

THOMPSON.—On November 21st, at 2 Greencroft Gardens, N.W., the wife of Ralph Thompson, Ch.M., F.R.C.S., of a son.

UNITT.—On November 21st, at Quorn, Leicestershire, the wife of James Arthur Unitt, L.R.C.P., M.R.C.S., of a son.

Marriages.

ENGLISH—SAMPSON.—On November 20th, at Lenton Parish Church, Howard English, M.D., F.R.C.S., of Crewe, eldest son of James English, of Lurgan, to Flora, daughter of Walter Sampson, The Park, Nottingham.

MACKIE—BALL.—On November 22nd, at St. Paul's Cathedral, Calcutta, Captain F. Percival Mackie, I.M.S. (formerly K.G.O. Central India Horse), son of the late Rev. John Mackie, Rector of Filton, Glos., and of Mrs. Mackie, Compton Greenfields, to Gladys May, younger daughter of W. J. Ball, Upper Belgrave Road, Clifton, Bristol.

THOMSON—LEISHMAN.—On November 19th, at the Anglo-American Church, Beyrout, Syria, Eric A. Thomson, M.B., Ch.B., to Rose, youngest daughter of the late Henry Alexander Leishman, of Lorne, Queensland.

Deaths.

HUGHES.—On November 19th, at Marine Terrace, Aberystwyth, Dr. Richard Hughes, formerly of Llanilar

McKELLAR.—On November 17th, at "Woodleigh," Preston Park, Brighton, Eliza Mary, beloved wife of Surg.-General McKellar.

OWEN.—On November 17th, at Middlesbrough, from pneumonia, Cyril Hayward Owen, eldest son of the late Francis Owen, M.R.C.S., L.R.C.P., of Sunnyside, Leatherhead, Surrey, in his 51st year.

WELLS.—On November 14th, at Eldon Terrace, Woodhouse Lane, Leeds, George Lee Wells, M.B., B.S.Lond., M.B., Ch.B.Leeds, F.R.C.S.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, DECEMBER 3, 1913. No. 23.

NOTES AND COMMENTS.

The National Medical Union. AT a conference of delegates held at the Waldorf Hotel, Aldwych, on Saturday last, under the presidency of Mr. William Coates, C.B., of Manchester, it was unanimously resolved upon the motion of Mr. G. A. Wright, F.R.C.S. (Manchester), seconded by Dr. H. B. Greene (Wandsworth), to form a federation, with a central organisation in London, to be called the National Medical Union, the principal condition of membership to be that applicants for membership shall not be on the panel, directly or indirectly. All the federated local associations will have local autonomy. It was agreed that the subscription to the central organisation shall be one guinea for each member. Mr. Wright and Professor Russell (Edinburgh University) were elected presidents, and Dr. John Playfair (Edinburgh Medical Guild), Mr. W. Coates (the chairman of the conference), Dr. Bernard O'Connor (member of the London Medical Committee), and Dr. Greenyer (Brighton), vice-presidents of the union. Dr. Brassey Brierley (Manchester) and Dr. H. Oppenheimer (Hampstead) were elected treasurers, and Dr. R. Carswell (Wandsworth) and Mr. E. Arthur Dorrell (secretary of the London Medical Committee) were appointed secretaries. A provisional committee, representing the non-panel associations which sent delegates to the conference, was chosen, and it was arranged to establish central London offices for the union temporarily at the Waldorf Hotel. The chairman of the conference declared that the Insurance Act was a menace to the national health; and Sir Henry Burdett, who was present, said the occasion was a momentous one in the history of the medical profession. It was resolved to send messages of sympathy to the medical profession in Germany in its struggle against its position under the German Insurance system, and to the non-panel doctors in Wisbech who were the victims of the hostile demonstration recently.

The Government of the R.C.S. of England. THE recent annual meeting of Members and Fellows of the English Royal College of Surgeons has not materially weakened the hands of the present autocratic government by Council and Fellows. The attacking party have most of the argument on their side, but for all that it seems there is some truth in the assertion that there is much less unanimity and ardour in their ranks than was formerly the case. Let us see what two friends of the cause of the Members have to say about the matter. The *Lancet*, in its issue of the 29th November, professes the same friendliness to the reformers that it has always proclaimed. At the same time it laments for the space of a column the falling-off in the "vitality and conviction" of Members as to the necessity for change. Further, with regard to the arguments advanced by the college authorities, it remarks: "It is probable that these reasons are shared to-day by many more Fellows and Members than was the case twenty years ago, and this is the point which those working in the cause of reform appear to miss, despite the evidence." The time-serving policy implied in those words would have made the elder Wakley pale with anger. The *Lancet* of his days was not wont to mince matters when dealing with the party of privilege that held —and still holds—the reins of power in the English College.

Another Warning. IN the same issue of the *Lancet* appears a letter from Mr. Willmott Evans which deserves notice, as it comes from a Fellow who has always been a consistent upholder of the College. He bewails the tone of the Members and the way in which their case has been presented. The criticism of the finances of the College, he says, was "unintelligent." This warning may be of value in the future tactics of Members, who will be gratified to learn that Mr. Evans still supports the principles of the right of Members to vote for members of the Council and to sit on the Council. Why should not a great chartered corporation be compelled to present a detailed account of its stewardship at stated times? Can any supporter of the present privileged system of College government deny that there have been passages in the past history of the College which suggested most strongly the crying need of some such check on the expenditure of that body. If such occasions have once arisen, why should they not arise again? The funds of the College are mainly derived from Members, and it would seem only a fair and proper thing that they should have some sort of voice in the spending of it.

A Cause for Revolt. THE Royal College of Surgeons of England is one of the main props of the many-portal system of medical qualification. Under the present absurd system it is absolutely essential for any surgeon to take its Fellowship should he aspire to a post in any one of the important English hospitals. Some day it is to be hoped that Licentiates and Members will secure a proper representation not only in the English, but in all other Royal Colleges. Then, and only then, is there any likelihood that these Council-ridden bodies will take any interest in the protection of their constituent Members and Licentiates. Then, too, will be elected on the General Medical Council representatives of the main body of diplomates, and not, as hitherto, of the small knot of privileged persons who are the irresponsible rulers of the College, with all the associated advantages of place, emolument, title, fame, honour and glory. The whole of this mediæval survival is grotesquely out of touch with modern views and tendencies. The interests of the many must no longer be sacrificed to the personal aggrandisement of the few. Meanwhile, it is to be hoped that the faithful among the Members will not cease from bringing along their annual resolution. Some day, perchance, a new Wakley and a new journal will come to their aid. As to the falling-off in the ardour and the number of the reformers, we know of no means whereby any such changes could be definitely ascertained. On this occasion we beg leave to doubt the usual accuracy of our contemporary the *Lancet*. Even were such a diminution established, the cause survives—an abuse of corporate government privileged and unjustifiable as any that ever yet inspired revolt.

The Will to Live. Every medical man has come across cases of injury or illness in which the patient has succumbed apparently from no other reason than mental inertia. There has been no strong desire to get well, and in the absence of that powerful motive force the sick person has quietly gone under without seeming to offer the least resistance. It is in some acute disease, especially in which a crisis occurs in its course, that the influence of the mind over the body is well seen. How many times have the words of the medical attendant, "You are going to get perfectly well," spoken in a hopeful and impressive manner, acted as a magic stimulus to flagging vitality, and from that moment the downward progress has been arrested. In the case of an airman, who was seriously injured at Hendon a few weeks ago, it is reported in the daily press that he "willed himself hard to live" as soon as he partially recovered consciousness after the smash. He had sustained a bad compound fracture of the leg and was suffering severely from shock, but, to his joy, "the blackness began to lift." The occurrence of minor degrees of faintness or palpitation can sometimes be prevented or postponed by a determined effort of the will, and there is no reason to suppose that more serious derangements of bodily function may not be similarly influenced. At any rate, the power of resistance to death inherent in all men should be assiduously stimulated and encouraged in moments of physical weakness by every possible means, psycho-therapeutic included.

LEADING ARTICLES.

LONDON HOSPITAL APPOINTMENTS.

Now that the National Insurance Act has thrown the affairs of the medical profession more or less into the melting pot, it is of interest to speculate upon the future of hospital staff appointments. Under present conditions the system of appointment and tenure of these posts throws the door open to many abuses of a nature that deserves the attention not only of the medical profession, but also of the outside public. First of all comes the question of limiting the honorary staff appointments to the holders of particular degrees. The merits and demerits of this particular point have been worn threadbare, but the practice is too firmly rooted to be readily abolished. In England, needless to say, almost all the important hospital medical staff appointments are restricted to holders of the higher qualifications of the Royal College of Surgeons of England and the Royal College of Physicians of London. How is the cause of medical relief to be advanced by this careful protection of the financial interests of two colleges? How is science benefited by the exclusion from such honourable and educational positions of the members and licentiates of those corporations, as well as of the graduates of all British universities and the members of Scotch and Irish colleges? The fact of the ineligibility of, say, some three-fourths of the medical profession for the chief English hospital appointments is in itself an insult to the policy of the State which has sanctioned the establishment of more than a score of qualifying corporations. Should a State medical service become an established fact it may be anticipated that its hospitals will be manned by medical men irrespective of the source of origin of degree or diploma. On the whole it seems fairly obvious that the much-abused many-portal system of medical qualification owes its survival mainly to the vast collegiate interests that are vested in its survival. Another defect in the hospital world is the fact of non-payment for medical services. As things go, the young man having attained a high-standard qualification with a great expenditure of time, labour and money, and having gained a coveted post on a hospital staff, is obliged to give years of arduous and self-sacrificing work without remuneration. It is unfair that any man should be subjected to an imposition which is unparalleled in any other walk of life. It may be said generally of hospitals that everyone is paid directly or indirectly for services rendered, except the members of the honorary staff upon whom falls the heat and burden of the day. The philanthropists who administer the affairs of the charity are rewarded by social prominence and in some instances by titular distinction. Large fortunes are made out of the voluntary medical charities of the United Kingdom, with their vast consumption of drugs, medical appliances and the vast array of articles needed in the medical and the domestic equipment of such institutions. The administrative staff are, as a rule, fairly paid. It is only when we come to the very men without whose aid the charities could not exist that the purse strings are drawn tight, and essential services are acknowledged by vague references to the "humanity of the profession" and the like. Happily, in the case of school medical and of tuberculosis officers, medical referees and other recently created appointments a more or less adequate salary has been fixed. It is a curious fact that in London the tacit injustice of the unsalaried hospital post has been condoned by a small annual allowance. That plan is adopted in a few of the large hospitals, and we have no hesitation in saying that it would be of the greatest possible ultimate value to the public, as well as to the cause of medical science and to the patients, were an adequate salary to be attached to all hospital posts. The question of the proper administration of medical charities, according to their own rules and regulations or those of their charters, is another matter that demands attention. All who are familiar with the inner life of London hospitals, to take that part of the kingdom as an example, know that from time to time gross instances of injustice are perpetrated by these governing boards. Now and then a protest is made in the law courts, but for the most part the aggrieved persons find themselves compelled to suffer in silence. It is curious that the King Edward and the other metropolitan distributing agencies have not constituted some sort of court of informal appeal, before which complaints could be brought of official breaches of hospital rules and regulations. Years ago a fight was made by one or two persons against great odds to prevent the sale of a special hospital that stood in Hanover Square. The selling price was sent up by several thousands of pounds. The support of the great funds was not denied those who sold the enormously valuable freehold site of the hospital. Will the King Edward Fund venture to institute an inquiry now into the present value of the ground site concerned, and compare that lost birthright with the terms and stability of the substituted leasehold premises at a distance? The sale was implicitly sanctioned by the large grants made by the King Edward and the Hospital Sunday Fund. Are they satisfied with the result? It is significant that the hospital surgeon who resisted the sale was compelled to resign his post, the duties of which he had ably and faithfully discharged for many years. There is little doubt that large profits are now derived from the developed site, but it is difficult to see why the hospital should not have let the land on lease instead of parting with its freehold. The Charity Commissioners, it is only fair to add, sanctioned the sale. In a later article it is proposed to deal with the abuses that sometimes attend the filling of vacancies to honorary hospital appointments.

CURRENT TOPICS.

The Health of the Navy.

It is gratifying to note that the improvement in the health of the Navy is increasing, as compared with the preceding five years. According to the statistical report for 1912, recently issued as a Blue Book, there has been a substantial decrease in the cases of venereal disease, to which only four deaths and 141 final invalidings are attributed. The increased use of salvarsan is responsible for the improvement in this direction. The case ratio for the year under review is again lower than the average ratio for the last five years, and the average loss of service for each person compares very favourably with the five years' ratio and also with that of 1911. The final invaliding ratio and the death ratio, however, are slightly increased in comparison with the averages for the last five years, but the increases in each instance are only fractional. The total force, corrected for time, in the year 1912, was 119,540, and the total number of cases of disease and injury entered on the sick list was 76,815, which gives a ratio of 642.58 per 1,000, a decrease of 24.1 as compared with the average ratio for the preceding five years. The average number of men sick daily was 3,008.23, giving a ratio of 25.16 per 1,000, a decrease of 2.51 in comparison with the previous five years. The total number of days' sickness on board and in hospital was 1,101,013, which represents an average loss of service for each person of 9.21 days, a decrease of .88 as compared with the average for the last five years. The total number finally invalided was 2,023, of whom 98 were invalided after refusing operative treatment. The ratio per 1,000 of final invalidings was 16.92, an increase of .48 as compared with the average for the previous five years. No fresh cases are recorded under the heading "Wounds in Action," but two men are shown as invalided, one of whom sustained a bullet wound of the head in the Solomon Islands during 1911, and was invalided for facial paralysis and deafness following upon his injury, while the other was invalided for bullet wound of the thigh with fracture of the femur received in the Persian Gulf during 1910. It would be a good thing if the ventilation of seamen's quarters were to receive greater attention from the authorities than at present appears to be the case.

"Doctoring."

A correspondent in the *Westminster Gazette* has recently taken exception to the expression "unscrupulously doctored," as applied to photographs. He states very rightly that, as a medical man, he objects to the use of the word "doctored" employed in this sense, for "the implied wilful falseness and cheating for gain . . . are not the special accomplishments of doctors." This is perfectly true, but so is the fact that the popular use of the term "to doctor," or "to doctor up," as applied to things rather than human beings, carries with it a certain stigma of falsity. A person or an animal may be doctored or dosed with physic, in the sense of being patched up or healed; whereas a photograph or a painting may be doctored or faked—that is, deliberately altered or "toned down" to convey some totally different impression of the object or scene to that really existing. Similarly, pepper may be doctored or adulterated with ground datestones, and butter with animal fats. The word, therefore, is capable of many interpretations. In its degraded significance it would certainly be better if a synonym were employed, so as to avoid the suggestion of connection with medicine. Here is a matter for etymologists to consider.

The Treatment of Incipient Insanity.

The management of the so-called border-land case, in which it is almost impossible to determine the precise point at which sanity ends and insanity begins, demands considerable tact and wisdom on the part of the medical practitioner. In private practice it is easier to ensure that a discreet supervision will be exercised over the patient than in the case of a pauper who is gradually developing symptoms of insanity, but who has not yet reached the point where certification is imperative. At both ends of the social scale the same difficulties of diagnosis constantly present themselves. The subject was dealt with by Dr. Robert Armstrong-Jones, in a lecture delivered before the Medico-Legal

Society last week, on "The Rational Treatment of Incipient Insanity and the Urgent Need for Legislation." It is comparatively easy to prevent the small aberrations of conduct from becoming fixed habits, and to check the growing want of control exhibited by many patients in the earliest stages of mental disorder. Time is needed, however, for favourable influences to work, and it would be far better if the period of detention without certification authorised in England under the Lunacy Act could be extended from the present one of twenty-eight or thirty-one days to one not over six weeks, as is permitted by the authorities in Glasgow, for the special treatment of incipient insanity. In the Poor-Law Infirmary of Glasgow early mental cases are treated in separate wards, with such gratifying results that it is shortly proposed to erect a special building for such patients that will be more suitable for their needs. Dr. Armstrong-Jones pleaded for fresh legislation in the matter whereby it would be possible to place persons whose insanity is doubtful in specified homes or hospitals, suitably registered, so far as London is concerned, by the London County Council, and recognised for the purpose by the Lunacy Commissioners. Were such a scheme adopted, there can be little doubt that the public would be greatly benefited thereby.

The Diagnosis of Fractured Skull.

THE difficulty of distinguishing between concussion of the brain and a fractured skull in cases of severe head injury is known to every medical man. The occurrence of bleeding from the nose or ear—especially the latter—is often regarded as being strongly suggestive of fracture in the absence of more definite signs. In doubtful cases, where it is impossible to decide at the time of admission to hospital the real nature of the injury, the patient is rightly given the benefit of the doubt—that is, he is treated as though he were suffering from the graver condition. It is very seldom that any objection is ever taken by the patient's friends to extra care and caution being bestowed upon him, or even to being informed that he is suffering from some grave injury or disease when the subsequent course of events shows that the diagnosis was wrong. At an inquest held at Southwark the other day upon a man who died in the street after having been treated in Guy's Hospital for three weeks for supposed fractured base, the son of the deceased expressed surprise and dissatisfaction when he learned that his father had only concussion of the brain, and not a fracture, as was originally diagnosed. This ingrate was rightly taken to task by the Coroner, who pointed out that it was fortunate that the man had not a fractured skull, which was proved at the *post mortem*, and that medical men, like anybody else, were liable to make mistakes. Here was a mistake, however, on the right side, for the cause of death was found to be heart failure and to be unconnected with any cerebral lesion. There is no satisfying some people.

The Causes of Fatigue.

THE mechanism of the production of "that tired feeling" has long interested physiologists. In these days of rush and tear there is probably a good deal more over-fatigue, which is perilously akin to strain, and considerably less of the old-fashioned dog-tiredness, such as results from indulgence in a day's sport, experienced by our forefathers. And yet the development of sarcolactic acid goes on in the muscular system of the body no matter how this is exercised. In the case of other organs and tissues, there are probably toxins at work, also of a chemical nature, which impair the delicately-adjusted vital mechanisms. These were hinted at in the Lady Priestley Memorial lecture delivered last week before the National Health Society in London, by Professor W. Stirling, of Manchester. The fatigue problem is one of great interest to teachers and to the child at school. Thus it has been found that mathematics are the most, and drawing and religion are the least, fatiguing of the various school subjects, history and geography occupying an intermediate position. The time of day has an important influence upon mental work. In the case of school children the hours between ten and twelve are usually the most favourable for the tackling of a difficult subject. Older people vary considerably in their power to concentrate upon a mental problem, some preferring to work before breakfast, while others find they can achieve better success late at night. The lack of oxygen has been shown by Professor Leonard Hill to be a potent cause of fatigue, as well as of somnolence. If the reserve power of an individual be rapidly drawn upon, without allowing sufficient time for recuperation, he will soon suffer from fatigue. An important practical outcome of our knowledge of the condition predisposing to fatigue is that, if employees are made to work in good hygienic surroundings, both they and their employers will be the gainers. The most economical production of labour is to be obtained by employing men only so long as they are at their best. When this stage is passed, and fatigue has manifested itself, true economy in work ceases to exist.

The Newcastle (Ireland) Hospital Again.

IT is with regret that we find it necessary again to refer to the affairs of the Royal National Hospital for Consumption at Newcastle, Co. Wicklow. Our readers will remember that last spring, under circumstances which were fully reported at the time, the consulting and visiting medical staff found it necessary to sever their connection with the hospital. This step was forced on them by the active interference by the managing committee in questions of medical treatment. The action of the medical staff received the formal approval of the Fellows of the two Royal Colleges of Ireland. At the same time certain members of the managing committee—including its medical members—who differed from the action of the majority of the committee, resigned their seats as a protest. Since that time the managing committee has taken no step to set itself right with the profession, or to withdraw from the position it had taken up of having the right to dictate to the staff as to the treatment to be adopted in the hospital. It is with regret, therefore, that we observe from a newspaper report that certain medical men have now been induced to accept seats on the managing committee. By this step they condone the previous actions of the committee—actions which one of them, at least, joined in condemning last spring.

The Craving for Tea.

IT is said that every person craves for something —whether it be wealth, love, or drugs. Of the latter, alcohol must still hold the first place, though we are told that in certain quarters the craving for tea is threatening to oust that for the stronger stimulant. According to the final report of the Irish Milk Commission, recently issued, it is stated that "the common use of tea and bread in place of milk and oatmeal tends to degeneracy, and it is for the welfare of the community that there should be a reversion to the older articles of food. To the difficulty of obtaining milk or buttermilk has been attributed the disuse of oatmeal, the neglect to make home-made bread, and the habit of tea-drinking." A craving for tea, it is stated, creates a repugnance to milk, and the tea-drinking habit is severely condemned. "In dealing with the tea-drinking habit, we travel in a vicious circle," state the Commission. "Speaking generally, tea is in the first place drunk where milk is difficult to obtain; then, because tea is preferred to milk, no serious effort is made to procure the latter. Most parents are aware that milk is a necessary food for infants, yet we found not infrequently that tea without milk is given to babies and young children because milk is not forthcoming. Children of three months old have been brought up on tea; they get accustomed to the taste of it, as a man gets accustomed to the taste of alcohol, and the habit becomes inveterate." Most out-patient medical officers of hospitals in London are familiar with the abuse of tea by the poor, especially in relation to the feeding of young children. It is a little stretch of language, perhaps, to speak of a "craving" in regard to what may be described as a harmless national beverage, for the desire for tea cannot be compared, for instance, with that for such a stimulant as morphia, either in its intensity or in its effects.

The Family Doctor.

THE family doctor is not passing away, for, although we are constantly hearing that this is the age of specialism, it is perfectly true that every day the specialist's dependence on the general practitioner becomes more complete. The *corpus vile* has been divided into as many water-tight compartments as an ocean liner, and the family physician is the only man able to play the iceberg and to sweep away the obtruded obstacles that ordinarily interpose between, say, the bacteriologist and the eye-man. There is, no doubt, a tendency towards the department store idea of treatment. Several men representing different specialties work together. We see this practised every day to some extent, and the Mayo clinic employs no less than ten varieties of specialists in diagnosis who are available for every case that needs them. It must be soul-destroying work for a man to do nothing but administer and examine test meals all his life, but such a man probably knows all there is to know about test meals after a few years. This group diagnosis is surely feasible, but it does not do away with the family doctor. He is as necessary as ever and must be competent. He must realise, for instance, that it is important to send for a surgeon in the first twenty-four hours of appendicitis, and that 80 per cent. of growths in the mammary glands of women are, or ultimately become, malignant. The specialist may say "you press the button, we do the rest." The family doctor will always be depended on to know which button to press and when to press it.

PERSONAL.

H.M. THE KING has been pleased, on the recommendation of the Secretary for Scotland, to approve the appointment of Dr. Norman Purvis Walker, M.D., treasurer of the Royal College of Physicians of Edinburgh, to be an additional member of the Highlands and Islands (Medical Service) Board constituted under the Highlands and Islands (Medical Service) Grant Act, 1913.

DR. WALTER PETTER, M.B., has been appointed Assistant Physician to the Darlington Hospital.

MR. GORDON LEY, F.R.C.S., has been appointed Pathologist to the Chelsea Hospital for Women.

PROFESSOR SIR J. HALLIDAY CROOM has been elected President of the Edinburgh Obstetrical Society for the ensuing year.

DR. ARTHUR GEOFFREY BATE, of Hove, has been appointed Consulting and Operating Surgeon to the Brighton Workhouse.

DR. CUTHBERT GERALD WELCH, M.D.Lond., D.P.H., has been appointed Chief Tuberculosis Officer to the Bedfordshire County Council.

MR. J. ST. J. STEADMAN, D.P.H., M.R.C.S., L.R.C.P., L.D.S., has been appointed Assistant Dental Surgeon to the West London Hospital.

MR. H. MORRISTON DAVIES, F.R.C.S., has been appointed Honorary Surgeon to the City of London Hospital for Diseases of the Chest, Victoria Park, E.

THE Manchester Corporation Sanitary Committee have appointed Dr. S. Rupert Briercliffe and Dr. S. A. B. Porteous to be Tuberculosis Officers for the city.

DR. RACHEL HIRSCH, of Berlin, who is Chief Assistant at the University Clinic of Professor Strauss, is the first German lady physician to acquire the title and rank of Professor.

THE Home Secretary has appointed Mr. W. P. G. Graham, M.B., M.R.C.S., and Dr. G. F. Rogers, M.A., M.D., to be Inspectors of Vivisection under the Cruelty to Animals Act, 1876.

DR. T. F. TODD, of Sunderland, was the recipient of a handsome presentation the other day at a complimentary banquet held at the County Hotel, Newcastle, by the North of England Branch of the British Medical Association, in appreciation of his valuable services rendered to the profession.

SIR THOMAS R. FRASER has retired from his position as Chief Medical Officer of the Standard Life Assurance Company, and the directors have appointed him Consulting Physician. Dr. Francis Darby Boyd, C.M.G., has been appointed Chief Medical Officer, with Dr. David Halliday Croom as assistant.

THE State Medicine Syndicate of the University of Cambridge have appointed Dr. Anderson, Master of Gonville and Caius College, Professor Sir Clifford Allbutt, M.D., and A. D. Thompson, M.D. (Edinburgh), to be members of the managing committee for the diploma in Psychological Medicine for the three years ending December 31st, 1916.

MR. EDWARD NETTLESHIP, F.R.C.S., of Longdown Hollow, Hindhead, Surrey, who died on October 30th, left estate sworn at £26,768 gross and £23,22 net. He left the following charitable legacies payable after the death of his wife:—£3,000 to St. Thomas's Hospital for the creation or augmentation of a fund for the endowment of lectureships in the medical school, and £1,000 to the Royal London Ophthalmic Hospital.

CLINICAL LECTURE

ON

EXTRA-UTERINE PREGNANCY. (*a*)

By J. M. MUNRO-KERR, M.D., F.F.P.S.Clasg.,

Muirhead Professor of Obstetrics and Gynæcology, Glasgow University; Gynæcological Surgeon, Royal Infirmary, Glasgow; Obstetric Physician, Glasgow Maternity and Women's Hospital; Hon. Fellow American Gynæcological Society.

THE case which I bring under your notice to-day is a typical example of extra-uterine pregnancy. The clinical history, which I shall read, and the physical signs, which those of you who examine will feel on making a bimanual examination, are absolutely characteristic of this condition.

Were all the cases as typical, the diagnosis of extra-uterine pregnancy would seldom present any difficulties, but unfortunately an atypical case is not infrequently encountered, and mistakes are readily made both in overlooking the condition and in diagnosing it when it does not exist.

The following is the summary of the clinical history of the case. Mrs. R., 37 years of age, was admitted to my wards in the Royal Infirmary on December 12th, 1912, complaining of a hæmorrhagic vaginal discharge which had been present less or more for the past six weeks. She was married twenty years ago; she has had nine children and three miscarriages; her youngest child is ten months old; her last "period" occurred eight weeks ago. Patient had amenorrhœa for some five weeks; then she began to bleed. Some three weeks after the uterine hæmorrhage commenced she began to have right-sided abdominal pain. She had two or three severe spasms of pain, but in the intervals a dull, aching feeling. She was sick, and vomited at each attack of pain. She occasionally complains of slight dysuria. Her general health is good, and her pulse and temperature are normal.

Now the striking feature in this case is the fact that the patient does not look ill, her pulse and temperature are normal, and she is of good colour and consequently does not appear to have had any severe internal hæmorrhage. The explanation of this state of matters is that the patient has come under our care before rupture or tubal abortion has taken place. I should be very much surprised to find much blood in the pelvic cavity in this particular case. Now it is of the greatest importance that you should appreciate this stage of the disease. Most practitioners whom I meet, and nearly all students whom I question, have the idea that the symptoms of extra-uterine pregnancy come on suddenly, and that the woman is immediately prostrated by collapse from the sudden giving away of the gravid sac. Undoubtedly such a type, which many of us refer to as the "fulminating type," is occasionally encountered—the woman is suddenly seized with acute pain and collapses, but it is very rare indeed, and becomes increasingly rare the more one sees of extra-uterine pregnancy and the more carefully one goes into the histories of the cases. Almost invariably before tubal abortion or rupture occurs, there are more or less distinct symptoms of pelvic and abdominal disturbance, which if carefully considered, should lead one to suspect extra-uterine pregnancy.

As a rule the mistakes made result from the physician in attendance failing to appreciate the symptoms prior to the occurrence of rupture or abortion. Sometimes, of course, the medical attendant is absolutely free of blame, because the patient herself, owing to the fact that the symptoms have been so slight, has not summoned him until the graver symptoms of collapse and internal bleeding have occurred. Now let us examine the symptoms complained of by this typical case before us, and first of all let us consider the pain which she has complained of. You see this patient has been complaining of abdominal pain for a matter of fourteen days, that the pain has been paroxysmal in character, and whilst situated in the lower part of the abdomen has been specially pronounced on the right side. Sometimes she has been almost free of pain, but at intervals the pain has returned. The paroxysmal pain is caused by spasmodic contractions in the uterus and right Fallopian tube, and the dull, aching pain which she has sometimes experienced is due to hæmorrhages into the wall of the tube. In tubal pregnancy, owing to the destructive effect of the trophoblast, numerous hæmorrhages occur into the wall of the distended tube, and this gives the feeling of constant aching. In addition to the pain referred to, the patient has had slight dysuria; this, too, is very frequent in cases of extra-uterine pregnancy. Before the tube ruptures it is generally slight, but after rupture, and where there is a large collection of blood in the pouch of Douglas, there may be retention.

Another pain not present in this case, but specially marked where there is much blood in the pouch of Douglas, is rectal tenesmus. I have only observed this in a marked degree where there was a considerable amount of blood in the pouch of Douglas pressing on the rectum.

As regards pain, then you always have a dull, aching pain, with generally periods of exacerbation; you frequently have dysuria, and you occasionally have rectal tenesmus.

The second symptom present in this case is hæmorrhagic vaginal discharge. Here it came on before the pain started, but in most of my cases it has commenced after the attacks of colicky pain. The blood for the most part comes from the uterine decidua, which becomes partially separated. It may, of course, occasionally come from the tube. It is very apt to be confused by the patient and by the doctor in attendance with an irregular or excessive menstrual period. Now, here in this particular case the patient has missed one period, but a week after an expected period uterine bleeding occurred.

Generally speaking, there is a period missed, but sometimes the uterine bleeding comes on a day or two before the period, and so naturally the period is considered to be a little premature. In such cases this symptom is rather disturbing and is liable to throw the physician in attendance off his guard. But in the cases commonly encountered where one period is missed and hæmorrhage comes on at an unexpected time, the condition should arouse suspicion and should be fully investigated. When a woman, otherwise healthy, misses a period, pregnancy should always be suspected; and if she has pain and vaginal hæmorrhage, extra-uterine preg-

---

(*a*) Delivered in the University Gynæcological Department of the Royal Infirmary.

nancy should be thought of. I need not remind you, of course, that uterine abortion will present similar symptoms, so similar that only by careful bimanual examination is it possible to determine which of these conditions exists. Many mistakes are made in this connection; as a matter of fact, in most of the cases of extra-uterine pregnancy to which I have been called in consultation the attendant at one period of the case has looked upon the condition as an abortion. Again let me repeat that it is necessary to make a careful bimanual examination, if need be under an anæsthetic, before one can be certain whether the pregnancy is uterine or extra-uterine.

The third symptom complained of by our patient is a feeling of sickness and faintness, especially when she had the attacks of abdominal pain. These sensations are really due to the distension and painful contractions of the tube. As you know, nothing depresses an individual so much as abdominal pain and uneasiness.

Another symptom sometimes present, but absent in this case, is the expulsion of a decidual cast from the uterus. As you are aware, the mucous membrane of the uterus in extra-uterine pregnancy undergoes a marked hypertrophy—a decidua forms. Now it is not uncommon to get this decidua expelled during the painful contractions in the tube, but so uncertain is this symptom (personally, I have only encountered it in 16 per cent. of my cases) that it is of very uncertain value. In this particular case there is no history of its having been expelled, and as a matter of fact in actual practice it either escapes notice, coming away piece-meal in the blood clot, or is expelled some days after operation.

I have said that the physical conditions in this case are also characteristic. Let us examine her. On bimanual examination you can readily define the fundus and the uterus displaced somewhat forward. The uterus you will feel enlarged and moderately movable. Behind it and to the right side you will, I think, be able to define a swelling about the size of a Tangerine orange. This swelling is rather soft, and yet it can hardly be described as elastic; it is not freely movable, and yet cannot be said to be absolutely fixed. It is quite distinct from the uterus. As the patient is under an anæsthetic, you cannot determine whether it is painful or not; but as a mater of fact, when I examined her yesterday, it was distinctly painful. That is an important feature in most ectopic sacs.

You observe that the tumour, whilst situated at the right side, is also lying behind the uterus. This is the general rule. You also observe that the appendages on the left side are readily palpable and feel normal. Now the only conditions other than extra-uterine pregnancy that could be present here is an intra-uterine pregnancy with a co-existing ovarian cyst—pyo-salpinx—appendical abscess.

An appendical abscess can be excluded because of the history of the case and because the rigidity of the abdomen is not extreme; besides, the swelling is well defined, and its upper limit can be well defined; in other words, there is no diffuse inflammation of the surrounding parts. Pyo-salpinx can also be excluded because there is no history of old standing pelvic inflammation, and because the appendages on the other side are, as I have stated, normal—unilateral pyo-salpinx is comparatively rarely encountered.

A small ovarian cyst with an intra-uterine pregnancy cannot be absolutely excluded. But the whole history of the case so clearly points to extra-uterine pregnancy that I am disposed to make an absolute statement that extra-uterine pregnancy is the condition we have to deal with here, and that the tube has probably not ruptured.

We shall now operate on the case, and you will see for yourselves the condition of matters in the pelvis. My assistant and myself will now change into fresh rubber gloves and put on fresh sterilised gowns, caps, and masks. The skin of the abdomen we sterilise by means of a 5 per cent. iodine solution, and the patient is placed in the Trendelenborg position.

Now you see the abdomen opened by a median longitudinal incision; here are loops of bowel connected with the right appendages, but very easily separated. The sac, as it is exposed, is obviously connected with the tube, and is adherent to the ovary. On looking at the tube you see the fimbriated end, and projecting from that end a red mass. We have a perfect example here, therefore, of tubal pregnancy in process of aborting. There is no rupture of the tube; the tube wall is dark red in colour owing to the numerous hæmorrhages into its substance, but so far no actual rupture has taken place. There is, as you will see, only a small quantity of free blood in the pouch of Douglas; she has therefore lost very little blood.

Now I think in this case I shall be able to save the right ovary and remove only the gravid tube. You might very naturally say: Why not shell out the ovum from the tube as you would in a uterine abortion, and leave the tube intact? Well, I have tried that method of treatment once or twice, but have always found that a considerable oozing continued from the tube so emptied. This may be negligible, but so far I have never closed up the abdomen and left the tube behind, although this has been done on several occasions by different operators.

Now you observe I examine the left adnexa and appendix. They are obviously quite normal. I now, you see, swab out the pouch of Douglas and pour in a little saline solution. The abdomen I close in layers. I apply three through-and-through silkworm sutures as splint stitches. I close the peritoneum with continuous catgut and sheath, and the rectus muscle with interrupted sutures. The edges of the skin you see I coapt with Michelle's clips. I dab spirit over the surface of the wound and place a strip of gauze over it, and then tie the splint silkworm sutures over the gauze; lastly, a light gauze dressing is applied over the wound, and the patient is put back into bed.

But before we separate, just look at this specimen. You will see for yourselves it is a very beautiful example of a tubal abortion. The implantation of the ovum must have been in the ampulla of the tube; now, when such an implantation takes place, the ovum buries itself in the tube wall by means of the trophoblast. Numerous small hæmorrhages occur into the wall at the implantation site just as they do in the wall of the uterus when the ovum implants itself there. But while the uterus is properly constructed for the implantation of an ovum, and the destructive effect of the trophoblast is inhibited by the decidua which forms there, it is quite otherwise where the ovum is implanted in the tube. In the tube the trophoblast has free play for its destructive influence.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Professor Hutinel, M.D., Physician to the Hôpital des Enfants Maladies, Paris. Subject: "Meningeal Hæmorrhage in Childhood."*

ORIGINAL PAPERS.

A PLEA FOR A COMBINED SURGICAL AND MEDICAL TREATMENT OF PULMONARY TUBERCULOSIS.

By W. C. MINCHIN, M.D., B.Ch.

The attention which has been recently directed toward the mechanical treatment of pulmonary tuberculosis in The Medical Press and Circular cannot fail to be of much interest to the profession. Dr. Tucker Wise writes to encourage those who have become tired of using tuberculin to adopt the excellent postural method of treatment which he has recommended. The gratifying results which are often obtained are no doubt due to its getting rid of fluid of the nature of "shut-away fluid." If it does not actually get rid of it, it prevents stagnation by producing some movement of the fluid. I think it is necessary, for the perfect development of the *Bacillus tuberculosis*, to have a stagnant medium in which to grow luxuriantly. Any disturbance, then, of their formed colonies, is likely to weaken or destroy them. A striking example of this has been presented to most practitioners from time to time when, on finding a tuberculous mass in the abdomen, a surgical operation was deemed necessary, but on opening the abdomen it was found advisable not to proceed further, owing to the extent of the disease. The result has often been a cure, merely from the mechanical disturbance, washing or drainage, which left the bacilli at the fountain-head no longer in a stagnant condition. By the adoption of a postural method of treatment we can only hope, however, to get rid of accumulations of fluid from the bronchial tubes and their dilatations, and an occasional cavity in the pulmonary tissues which has an opening so situated that by gravitation it can be emptied. It may be by tilting, in a manner similar to the emptying of a bottle from the top, or of a hot-water bed jar from an opening in the middle, or of a tea-pot from one at the bottom, or combinations of these. When cavities can be so emptied, the great difficulty with which we are met is that we do not know where the openings, when they exist, are situated, nor how best to pose our patient.

In those cases where the openings are not so situated as to be readily emptied, or when a cavity containing pus exists in the lungs without any opening, or when such cavities are multiple, I think it is clear that no postural method can be entirely satisfactory, even though it cures some patients, and relieves symptoms in others by clearing away some fluid of the nature of shut-away fluid. It is then as an adjunct, rather than as a substitute, that this treatment will show its best results, and I believe it to be a valuable adjunct to any treatment. What we want is a rational procedure which will show a reasonable chance of cure in every case. In all the varied remedies brought forward there is no treatment amongst them which will do this, although every one of them has its merits and its cures to claim. The question we ask ourselves is: Why will any given treatment cure one case and be powerless even to relieve symptoms in another? Our powers of observation, so far as cause and effect are concerned, are more upset in pulmonary tuberculosis than in any other disease. In my opinion the curtain is raised and the view is clear when we come to consider the part played by "shut-away fluid." I have described "shut-away fluid" as a stagnant fluid having no exit and infected with the *Bacillus tuberculosis*, and I have endeavoured to explain elsewhere (*a*) my reasons for suspecting its presence. I think it is unreasonable to expect to sterilise the shut-away fluid contents of a pulmonary cavity by means of any serum or germicide taken internally, put into the blood-stream, or inhaled. These cannot be so applied that they can in any way affect the bacterial processes which are taking place within the fluids. To persist, then, in any of these lines of treatment in a case of shut-away fluid in the lungs is simply to look on while our gradually fading patient dies, unless nature steps in and causes a pneumothorax, or the contents of the cavity are discharged into a bronchial tube. Mechanical interference is necessary; but why should we rely on it alone? Surely if we express the shut-away fluid with an artificial pneumothorax or pleural effusion the time has come when serum or germicides can act. In these cases, as a routine, a cure can only be effected by a combined treatment. It is reasonable to expect that with a combined treatment there would be no necessity after the performance of an operation for artificial pneumothorax, when the fluid has been expressed, to keep the lung collapsed for such a length of time as is now customary. Many are of the opinion that the virtues of an artificial pneumothorax are due to the rest which the lung obtains; but from observing that often the temperature and other evidences of active disease are immediately put right after the operation, I think it fair to conclude that something has been expressed from the lung, and that the continued pressure prevents its re-formation. Instead of the continued pressure it would be reasonable to expect just at this stage that serum or many germicides would prevent the bacilli from lighting up the disease again when the pressure was relaxed and the gas drawn off. Experiments upon the dead lungs show that shut-away fluid can often be expressed without the lungs being completely collapsed. Dr. Allison and others have suggested the formation of an artificial pleural effusion which may yet be shown to be preferable to a pneumothorax, but the object of each is identical. The question before the advocates of each is: What is the proper time to operate? It is clear that the earlier it is performed the better the chance of success, but then many early cases get well under more simple treatments, and, very naturally, patients shrink from such an ordeal as having their lungs collapsed if it is avoidable. I have formed a definite opinion upon this point which I trust will be accepted as my apology for occupying so much space. I have found, as previously asserted, in The Medical Press and Circular, March 12th, 1913, that the oil of allyl is very deadly to the *Bacillus tuberculosis* in the human body. It saturates the human tissues and blood-stream in a manner which cannot be excelled by any serum. Its action is rapid, and in a case of pulmonary tuberculosis, if no shut-away fluid exists, a great improvement will be noticeable in a few weeks, and this will continue. If there be no improvement in three weeks under its influence in any given case, I have never seen either itself, any serum, germicide, or sanatorium treatment, do any good subsequently, and I believe we are dealing with a case of "shut-away fluid." This, then, would appear to be the time for mechanical interference, which, if employed thus early, would, I think, relieve us from the many disappointments met with through adhesions, and overtaxing the powers of the uncollapsed lung. I think that shut-away fluid fre-

quently exists in very early pulmonary cases which run a rapid course, and without mechanical interference these are hopeless from the first.

THE PLACE OF THE OPEN-AIR SCHOOL IN PREVENTIVE MEDICINE. (a)

By Sir GEORGE NEWMAN, M.D., D.P.H., F.R.S.E.,
Chief Medical Officer and Principal Assistant Secretary, Board of Education.

Sir George Newman said that the ventilation of many of the ordinary elementary public schools of the country was at present open to criticism. He gave instances of various schools showing that the amount of carbonic acid gas was in some cases double the quantity which ought to have been permitted, and he said these conditions were representative of what was taking place all over the country. The effect upon the child of a close atmosphere was deleterious. What was required was more blood circulation, more oxygen taken in, the lungs better expanded, and more food eaten. Consequently what they were aiming at in the open-air process was almost the opposite to what they were getting in the ordinary schools of the country.

In an open-air school a child would get cheap and nourishing food given to it at regular intervals and under suitable conditions. Scarcely enough importance has been attached to the value of proper rest in cases of surgical tuberculosis, and he showed pictures on a screen of patients at the Lord Mayor Treloar Cripples' Home and College, Alton, where the children got the full benefits of the best methods of rest and sunshine. This school was probably the best of its kind in the world. There children were kept in a position of rest from eighteen months to two and a half years, and the results obtained were far in advance of what had been hitherto obtainable by surgical interference.

Again, the hygienic way of life was a most important factor in the open-air school. Rest, work, and nutrition conduced to a healthy life. The exercise should be organised; the child should be trained to personal cleanliness, and it should be suitably occupied. In an open-air school a child got more individual attention than in an ordinary school, and the same applied to medical attention. Special educational methods were also required, because it was estimated that not less than 10 per cent. of all the children in the United Kingdom did not or could not respond to the ordinary methods of education. This special education required to be more objective—more manual—the child taught to do things instead of repeat them; and an endeavour should be made to get the child to express himself, and then to train him and educate him along that line. The open-air school was therefore for the dull and backward and retarded child, though not for the feeble-minded child.

Ferryboats had been used for open-air schools in New York, and it had been suggested that they should be used in London. But the same reason for utilising them in New York did not apply to London, and there were probably other reasons why ferryboats on the Thames would not be as satisfactory as open-air schools.

It was idle to think that open-air schools offered a panacea for all children. There was the difficulty of classification to begin with, and he thought the classification should be based on physical and medical grounds. There were difficulties as to the home influences, where a child slept at home in a bad atmosphere for eight or nine hours at night. A great deal of the malnutrition in children was no doubt due to the food, but not sufficient importance was given to the fact that a great deal of it was also due to their not giving the children in the great cities sufficient rest. One solution was residential schools, but of course they had the disadvantage of taking the child away from its home and its mother. The conditions of success in the open-air school were that there should be adequate organisation and suitable and proper equipment, proper medical supervision, co-operation on the part of the parents with the teacher in the open-air school, the admission of suitable cases.

Sir George Newman specified the diseases which ought to be dealt with in open-air schools, and showed a number of pictures of the little cripples at Alton, who are under the supervision of Dr. Gauvain, the chief feature of which was the remarkable application of splints of various types, and which were shown being applied in the "rest and sunshine treatment," which is the leading feature of this home. Dealing with the diseases which ought to be treated in open-air schools, Sir George Newman said that more than half a million debilitated and badly-nourished children were really in need of treatment in these schools. It was also estimated that there were 15,000 children in this country suffering from some condition of tubercle who needed special treatment. Then there was the question of nervous diseases, which included chorea, or what was known as St. Vitus's dance, and mental dulness and retardation. Children with adenoids and bronchial catarrh also required special treatment, and thus it might be said that there were nearly half a million children in our schools who required the open-air process; other diseases which ought to be specially treated in these schools were rickets, various forms of heart disease, both functional and organic, in children. Further, there was a group of miscellaneous diseases, including oral sepsis, where the teeth were so bad as to set up a septic condition of the mouth, which led to a whole group of diseased conditions, and which might produce a lasting injury to the child. Lastly, spinal curvature ought to be a subject of special treatment in the open-air school.

At Alton, in Hampshire, Sir William Treloar and his friends had secured a building and turned it into a hospital, and had not only adopted the process which had been applied at Berck, in France, but had greatly improved upon it, so that the Alton school was now probably superior to anything that could be done at the school in France, which treated upwards of 1,000 children. Much of the good result at Alton was undoubtedly due to the excellence of the nursing.

In conclusion, Sir George Newman spoke in high terms of the work being carried on by Dr. Gauvain at the Alton school, and as before mentioned, showed some pictures giving practical illustrations of the splints and the "rest and sunshine treatment."

PYELITIS. (a)

By CLAUDE FRANKAU, B.S.Lond., F.R.C.S.Eng.

I am endeavouring to-night to give you some account of a condition which has only been really studied fully during the last few years, and which from the obscurity and difficulty presented by many of the cases possesses considerable interest. By pyelitis is meant an inflammation of the pelvis of the kidney. Such inflammations are naturally rarely if ever confined to the pelvis alone, and a condition of inflammation of the pelvis and kidney substance or pyelonephritis is usually present.

(a) Second Chadwick Lecture delivered at the University of London, November 11th, 1913.

(a) Paper read before the Chelsea Clinical Society, November 18th, 1913.

ÆTIOLOGY.

Excluding tuberculous infection, which is a separate matter, and would open up an enormous field, and which I do not propose to touch upon to-night, from the point of view of ætiology, the cases may be divided into two classes :—

(1) Those due to a hæmatogenous infection;
(2) Those due to an ascending infection.

The hæmatogenous type of infection is the commonest —the organism most frequently found is the B. coli communis in 75 per cent. of the cases; staphylococci and streptococci are occasionally found, and such organisms as B. typhosus, B. pyocyaneus in rare cases. The condition is most usually unilateral, and although there may have been no apparent abnormality of the kidney prior to the attack it is not uncommon for some predisposing cause to have been present.

The more frequent of such predisposing causes are :—

(1) Congestion due to exposure with a resulting impairment of resistance;
(2) Unnatural mobility also causing congestion;
(3) Local trauma;
(4) The presence of foreign body—*i.e.*, a calculus;
(5) The irritative effects of drugs, poisons, or the toxins of disease.

That such predisposing causes are almost essential is affirmed by the well-known clinical fact that a healthy kidney can excrete organisms in large numbers without itself being affected, and from numerous experiments on animals in which it has been found that uninjured kidneys are not affected by the injection of organisms into the renal artery, whereas if the kidney is locally injured or is congested by producing venous obstruction, pyelitis and pyelonephritis supervene.

The focus of origin of the organisms may be apparent in the form of a boil, an ischiorectal abscess, or pyorrhœa; more often the origin is obscure; in such the focus is presumably intestinal, and the result of intestinal stasis.

Ascending infections per se with no obstruction to the outflow of urine are extremely rare—if they do occur at all they are the result of an extremely virulent organism; even in these cases proof positive of an ascent is wanting and the pyelitis may be hæmatogenous in origin.

The two great safeguards against an ascending infection are (1) the constant downward flow of urine in the ureters; (2) the valvular arrangement of the ureteric openings into the bladder which prevents regurgitation. It has been experimentally proved that the bladder on artificial distension will actually burst before any back leakage occurs through the ureters. Constant back-pressure from stricture or enlarged prostate or from pressure on the ureters from a pelvic growth or pregnant uterus destroys eventually one or both of these safeguards. Thus in enlarged prostate or stricture the constant over-distension of the bladder which may never be fully emptied destroys the valvular nature of the ureteric openings and allows of dilatation of the ureters, which in their turn are distended by stagnant urine.

An ascending infection either directly *viá* the urine or up the ropy mucus lining the ureters is easy to understand and there is no need to invoke the aid of the peri-ureteral lymphatics as is done by some writers. As will be shown later, constant back pressure also produces certain changes in the kidneys which makes them peculiarly liable to infection.

PATHOLOGY.

In the early stages of an acute hæmatogenous infection the whole kidney is enlarged and congested—the pelvis is hyperæmic and may show a purulent exudate. If the condition progresses miliary cortical abscesses or linear streaks of pus appear in the cortex—this may go on to gross abscess formation with complete destruction of the kidney. In hyperacute cases infective gangrene of the entire organ may occur.

If an acute attack subsides and a chronic condition supervenes the body of the kidney shows no evidence of active inflammation but fibrosis as a result of former infection is present. The pelvis shows thickening of its lining epithelium, which is reddened in irregular patches and may present the appearance of red velvet. In an ascending infection similar changes occur, but commence in the pelvis itself whence, owing to the antecendent back pressure effects, the inflammation rapidly spreads over the entire kidney substance.

SYMPTOMS, SIGNS AND DIAGNOSIS.

The two types described above—*i.e.*, the hæmatogenous and the ascending, differ to a considerable extent, and are best described separately.

The hæmatogenous type.—Here the onset is sudden and acute and is commonly ushered in by rigors which are repeated during the attack. Pain often of a severe character is complained of in one or both loins and the back; the pain may be referred down the course of the ureters. Headache, malaise and at times extreme drowsiness from toxæmia are noteworthy symptoms. The urine is voided with extreme frequency in small quantities; in severe cases pain on micturition is present and may be acute; this is due to a secondary infection of the base of the bladder. In several hyperacute cases I have seen severe and profuse hæmaturia.

On physical examination the face is flushed; the tongue is furred and signs of profound toxæmia may be present. The temperature is raised with intermittent pyrexia reaching as high as 105°, or even higher. The pulse is full and bounding, and of increased rate. Sweating occurs during the rigors. In the loin or loins there is extreme tenderness with muscular rigidity on palpation—this usually prevents any estimation of renal enlargement. Two spots of maximum tenderness can be elicited, one where the 12th rib cuts the outer border of the erector spinæ muscle; the other an inch and a half above and to the outer side of the umbilicus.

An examination of the urine is most important as a differential diagnosis often depends entirely upon this. In the early stages to casual examination there may be no abnormality apart from a trace of albumin; pus, both macroscopic and microscopic, is often absent, but a single drop of urine examined under a high power will be seen to be swarming with organisms. Pus may be absent throughout—this I have seen in one hyperacute case which happily resolved and eventually entirely recovered; a variable amount, however, is commonly present during the later stages of the acute attack. In the subacute stages microscopic amounts alone persist. The reaction of the urine depends on the organism producing the lesion. Unless suppression is commencing the amount of urine passed is normal or even increased. As mentioned above, hæmaturia is present in some cases and may be marked.

With appropriate treatment the acute symptoms subside with fair rapidity. The temperature falls, pain subsides, and the general condition improves. A complete resolution may occur in 7-10 days; it is more common, however, for a chronic condition to supervene, which is described later.

Fulminating cases with death in 48 hours are met with, but fortunately are rare; these are commonly due to the streptococcus or a strain of B. coli of exalted virulence.

A differential diagnosis has to be made from appendicitis, pyosalpinx, cholecystitis, typhoid and influenza.

A careful review of symptoms and signs with special attention to the condition of the urine obtained by the catheter should be sufficient—the most difficult cases to differentiate are appendicitis and cholecystitis from a right-sided pyelitis with acute onset. Cystoscopy—a proceeding to be avoided in acute cases, as it may cause an exacerbation of symptoms—will confirm the diagnosis where grave doubt exists. In unilateral cases intense congestion will be seen in the neighbourhood of the ureteric orifice on the affected side with swelling and œdema of the mucous membrane, and occasionally ulceration; the remainder of the bladder wall is comparatively healthy in appearance. In the latter stages and, more particularly if both sides are affected, there may be a universal cystitis—again, however, more marked around the ureteric orifices; in this condition the clue to the diagnosis is the character of the effluxes, which are cloudy from pus.

Treatment.

Complete rest in bed in a warm room is essential. A brisk mercurial purge, followed by a saline draft should be given to ensure a free action of the bowels. For the pain, relief can be obtained by the local application of antiphlogistine, spread upon lint or of thermogene wool. Morphia should be withheld if possible. Aspirin in 10 grs. doses is often efficacious. The diet should consist of fluids, preferably milk alone at first, with barley water or soda water. Large quantities of Imperial Drink are of the utmost value in flushing the urinary system. The urinary antiseptics are of little or no value in the early stages, and may indeed do harm, but large doses of the alkalies in simple or effervescing mixtures should be given for their diuretic value, and also with a view to producing alkalinity of the urine. An X-ray photograph should be taken as soon as the acute symptoms have abated to exclude the presence of a calculus as the causative factor. A culture of the causative organism should be made as early as possible in order to obtain an autogenous vaccine.

In the fulminating cases the question of a nephrectomy may arise; brilliant results have followed in apparently desperate cases. The remedy, however, is a severe one, and its necessity has been called into question since apparently hopeless cases often resolve under medical treatment. A nephrotomy with drainage of the pelvis is said to be a sounder operation, as less shock is experienced; the disadvantage of this procedure is the likelihood of a permanent lumbar fistula resulting. Operation is urgently indicated if acute symptoms persist, in spite of treatment, for more than 4 or 5 days, and the patient is becoming profoundly toxic, but it is doubtful whether nephrectomy is justifiable unless the condition of the other kidney has been ascertained by catheterisation of the ureter.

In many cases the disease is only met with or recognised when *in the chronic form*—the acute initial attack may have been neglected by the patient or a faulty diagnosis may have been made in the first instance. The characteristic symptoms of a chronic pyelitis are:—

(1) Lumbar pain—either unilateral or bilateral, and if the latter, often called by the patient "backache." This pain is intermittent with exacerbations, and varies from a "dull ache" to "sharp stabbing" pains;

(2) Increased frequency of micturition, both by day and night—this may be very marked and may suggest a cystitis;

(3) Associated with these symptoms there is often malaise, headache, and loss of appetite with associated loss of weight.

Relapsing acute attacks often occur.

On examination it is common to find a sallow, unhealthy complexion and a furred tongue, often abnormally dry in old-standing cases. Palpation may reveal tender enlarged kidneys, but this is not the rule. Tenderness at the "pelvic points," both behind and in front, is frequent. General lumbar tenderness is almost constant. The urine obtained by the catheter contains pus in microscopic or macroscopic quantities and is often turbid from bacteria. The reaction depends upon the causative organism. A differential diagnosis has to be made from chronic pelvic inflammations in the female, stone in the kidney and cystitis. The former two conditions may be excluded by careful pelvic and X-ray examinations; the latter can only be differentiated by cystoscopy. Cystoscopy in these cases is of the utmost importance, and, in my opinion, should be practised in every case in order to confirm the diagnosis.

The appearances are characteristic; the main portion of the bladder wall is normal. About the trigone, and more particularly in the neighbourhood of the ureteric orifices, there is injection; in the latter situation this may be intense and presents the appearance of flame-shaped patches just below and internal to the openings. The effluxes, if much pus is present in the urine, are cloudy; the frequency is often increased—this is the more noticeable if the condition is unilateral.

In all cases a careful bacteriological examination of the urine should be made with the view of preparing an autogenous vaccine. If the patient is unable to lie up exposure to cold and wet are to be carefully avoided. The diet should be full, but light; excess of meat, rich foods and strong tea are to be avoided, as also is alcohol, unless in small quantities well diluted. Large amounts of bland fluid must be taken by the mouth either in the form of barley water, Imperial Drink, or Contrexéville water; it is an admirable plan to take a pint of the latter water before breakfast on an empty stomach. The bowels should be carefully regulated by suitable aperients.

As to drugs the two most important are urotropine and the alkalies. If, as is usually the case, the urine is acid, large doses of potassium citrate—up to six drachms a day—should be given with a view to securing alkalinity of the urine. As soon as this is achieved, and it may take eight or ten days, the alkali is stopped and a mixture containing 5 grs. of urotropine with 30 grs. of acid sodium phosphate is prescribed. This method appears to give the best results as urotropine is most effective in an acid mixture.

The results of vaccine therapy are extremely variable, and I must say that, on the whole, I am disappointed by them. Yet at times brilliant successes follow this method—so much so that there is no doubt that full and adequate trial should be given over a prolonged period. Autogenous vaccines are essential, and the initial dosage must be small; reaction, if the dose is too large, may be severe. I have seen complete, but fortunately temporary, suppression follow an initial dose of 10 million B. coli vaccine. The usual initial dose of autogenous coli vaccine that I give is one million, the dose being gradually increased up to 80 or 100 million.

Two other methods are also available, and may be briefly referred to; in the first place, good results are claimed from irrigating the renal pelvis through a ureteric catheter. No particular difficulty presents itself in this method, but the results are, in my experience, not striking. The organisms are deeply embedded in the substance of the pelvis and kidney, and the comparatively weak solutions used (*i.e.*, Argyrol, ½ p.c., etc.), are not likely to be able to reach them.

Finally, as a last resource, operative measures may have to be undertaken. Two lines of treatment are possible:—

(*a*) Pyelotomy through a lumbar incision.

(*b*) Nephrectomy.

The former is applicable to very resistant bilateral cases with recurring and severe symptoms. A tube is sewn into the pelvis of the kidney, and the cavity is washed daily with antiseptic solutions. Good results are claimed, but I have no personal experience of the method, which is liable to be followed by a persistent sinus.

Nephrectomy is, of course, only possible in a unilateral case, and then only after making quite certain of the healthy condition of the opposite organ by catheterisation of the ureters. The method is drastic, but at times is justifiable. I have now in hospital a patient who suffered from a left-sided pyelitis for three years, which resisted all methods of treatment. She was in a miserable condition, and had become extremely emaciated and was worn out with pain. I ascertained that her right kidney was normal, and then removed the left kidney. The result is a striking success, and the patient in the two months following operation put on over two stone in weight.

Prognosis.

The immediate prognosis as regards life in acute cases may be regarded as good; the vast majority of cases tend to resolve more or less completely with appropriate treatment. The fulminating cases are, fortunately, rare, and the outlook is grave, especially if the infection is bilateral. Chronic pyelitis must necessarily be regarded as a condition which shortens life; the fibrosis which results from the inflammation in itself tends to impair the renal function, and any subsequent acute attack may be followed by the most serious results. Phosphatic concretions are also frequently deposited in kidneys the subject of chronic suppuration. The constant pain and toxæmia also act severely on the patient, who may actually die of exhaustion. Cases, therefore, which are resistant to treatment should be carefully examined, with a view to extirpation of the affected kidney, provided that its fellow is proved to be sound by catheterisation of the ureter.

The Ascending Type.—Where chronic back-pressure from some obstruction to the urinary passages has been present for a considerable period definite changes occur in the kidney: the pelvis and tubules show a variable degree of dilatation, and there is a marked increase of interstitial fibrous tissue. More or less marked signs of renal insufficiency are also present. The tongue is dry, the breath slightly offensive, thirst is complained of, and there is often a dull frontal headache. Large amounts of urine of low specific gravity with a trace of albumin are passed. If such a condition be present the advent of sepsis is fraught with the gravest consequences to the patient, and it follows that no case of chronic urinary obstruction should be neglected, and also that in the instrumental treatment of such cases the greatest possible precautions should be taken to secure asepsis.

The usual history of the disease in this type of case is that the patient who is known to have some urinary obstruction, either as the result of the use of a septic instrument or spontaneously following a neglected cystitis is suddenly seized with pains in the back with rigors. The temperature is raised in the early stages. The pulse is rapid and full. The tongue becomes rapidly furred and foul; vomiting may be marked and persistent: diarrhœa is often present. The urine becomes diminished in amount and is loaded with pus and albumin. If the infection is severe and anuria results, the temperature drops below normal. Headache and great thirst are complained of, and finally the patient dies in a state of uræmic coma. In less severe cases, with adequate treatment, the infection subsides, with, however, considerable further destruction of kidneys, which are already crippled and with a great tendency to relapse at a subsequent date.

Treatment.—In all classes of case it is of the utmost importance to relieve the obstruction to the outflow of urine. The safest and most satisfactory method of doing this is by suprapubic cystotomy. The operation is simple and can be performed in a few minutes under gas or gas and oxygen; very little shock results. In a few selected cases it may be possible to treat a stricture by internal urethrotomy, but it must be remembered that any interference with the urethra in such conditions is in itself likely to be followed by anuria, owing to the pronounced reflex mechanism which is involved. The obstruction having been relieved, the general condition of the patient must be treated. In mild cases hot fomentations to the loins, together with large amounts of fluid by the mouth and purgation are often sufficient. In severe cases more drastic measures may be necessary. If anuria and uræmia are threatening, hot-air baths should be given. Saline intravenous infusion is also of great value. If anuria has commenced, and the re-establishment of the urinary flow by the above means cannot be obtained, as a last resource a unilateral or bilateral nephrotomy with drainage may be attempted. The operation is a severe one and involves a general anæsthetic, but occasionally success follows. If the patient recovers from the attack, a course of urinary antiseptics and vaccine therapy should be instituted and continued for some weeks, after which time, if the general condition is good, the causative lesion may be dealt with by appropriate measures.

It will be seen from these remarks that the prognosis in these cases is grave; in fact, it has often been said that the onset of rigors in a case of urinary obstruction is the death sentence. Without perhaps going as far as this, it may at least be said that life is gravely endangered and the importance of early and adequate treatment of all cases or urinary obstruction may well be emphasised.

OPERATING THEATRES.

MIDDLESEX HOSPITAL.

Appendicitis.—Mr. Sampson Handley said that these cases illustrate both aspects of the practice of administering a purgative in the early stage of appendicitis.

Case 1.—A young man was seen by Dr. McDowell, of Wandsworth, for acute pain in the right iliac fossa of twelve hours' duration. His temperature was 102°, his pulse full and quick, and there was right iliac rigidity and marked tenderness. An ounce and a half of castor oil was administered and produced three good actions of the bowels. Simultaneously the pain disappeared, and the following morning the temperature was normal and the patient practically convalescent.

Dr. McDowell is a practitioner of great experience, for whose opinion Mr. Handley had a high respect. He is a convinced advocate of the value of an initial purge in appendicitis. Nevertheless, in Mr. Handley's opinion, nine successful cases of the type of Case 1 cannot outweigh the lesson of the case he was about to relate.

Case 2.—A little girl, æt. 10, was seized one evening with abdominal pain which persisted through the night. At 8 a.m. next morning her mother administered a purge which acted in a few hours. Simultaneously pain ceased and the patient said that she felt better. On the same evening, however, vomiting and pain returned. Mr. Handley saw her with Dr. W. P. Ker, of Clapham—whom, rather late, her parents had called in—on the next day but one. She had a temperature of 102°, and a pulse of 120, with marked rigidity and tenderness of the lower abdomen. Operation the same evening at the hospital disclosed a large pelvic abscess and an acutely inflamed appendix with a round perforation situated ¾ inch from its tip. It appeared from the history that appendical peristalsis produced by the purgative had precipitated the rupture, with temporary relief and subsequent aggravation of the symptoms.

Doubtless the commonest cause of acute appendicitis is the presence of some obstruction to the lumen which prevents the emptying of the appendix. If the obstruction is only a partial one, or one which can be overcome by the application of an extra push, a purgative will do what is necessary. But if the obstruction is one which cannot be overcome, rupture of the softened and inflamed appendix is the result. Until we are able to distinguish occlusion of the lumen from partial or removable obstruction, the use of purgatives was, in his opinion, indefensible.

A Note on Fluctuation in connection with an Operation on an Abscess.—Mr. Sampson Handley said that including the method it was his purpose to describe there were three ways of testing for fluctuation.

(*a*) The one-finger method. The student pokes the swelling with his right forefinger. The only advantage of this method is that the left hand need not be removed from the trouser pocket.

(*b*) The two-finger method. This is the method usually taught. The two forefingers are employed, one in an active and the other in a passive *rôle.* With one the swelling is pressed upon, whereupon if fluctuation is present the other finger is passively elevated. But across the course of a muscle, and in fat, this test gives a positive result which only the trained observer can distinguish from real fluctuation.

(*c*) The three-finger method was the one he wished to describe and to recommend. The tips of the two forefingers and of the middle finger of the left hand are firmly planted upon the swelling, marking out an equilateral triangle of an area rather smaller than the limits of the swelling. The right forefinger is next sharply pressed into the swelling at right angles to its surface. Fluctuation is present only if the two fingers of the left hand move away from each other horizontally in the plane of the skin at the moment when this is done. Any movement of the fingers in a vertical direction is to be ignored.

It would be seen that the method consists essentially in the artificial production of a true expansile impulse in an inelastic bag containing a fluid. It is evidently not infallible, for these conditions may be present to some extent in certain very soft encapsuled tumours.

This three-finger or expansile method of testing for fluctuation effectually distinguishes real fluctuation from the pseudo-fluctuation of substances such as muscle and fat. He would be interested to know if such a simple device had occurred to others than himself.

Mr. Handley said he had endeavoured to practise the virtue of brevity, which is so rare in medical oratory.

This virtue had been described as the soul of wit, a fact which may account by converse reasoning for the longitude of medical writings.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held Friday, November 14th, 1913.

The President, J. B. Coleman, C.M.G., M.D., F.R.C.P.I., in the Chair.

Dr. Coleman, in taking the chair for the first time, said it was his pleasing duty to thank the Fellows for the honour conferred upon him by electing him President of this Section of the Academy of Medicine.

SPONTANEOUS RUPTURE OF THE HEART.

Dr. A. R. Parsons, in showing this specimen, said that the patient first came to him complaining of flatulence and jagging pains in his right hypochondrium. In connection with the family history it was mentioned that the mother of the patient died from "burst aneurysm of the heart," and amongst the brothers and sisters of the patient there was a history of cancer of the stomach. The patient was engaged at hard manual labour. Physical examination showed nothing abnormal, nor did the urine contain any abnormal constituent. An examination after a bismuth meal discovered nothing abnormal. On examination of the contents of the stomach a positive reaction for blood was obtained, but there was no trace of free hydrochloric acid. He suffered from flatulence and food had to be taken every two hours. He was gradually increasing in weight, and would not consent to operation, as he insisted that his heart would not stand it. He became acutely ill at 2 a.m., and had to call in Dr. Winder. Dr. Winder suspected stomach trouble, possibly perforation; but physical examination showed that neither perforation nor peritonitis had occurred. The patient died shortly afterwards quite suddenly.

Dr. Parsons said that his diagnosis was some form of ulceration, although it could not be overlooked that the patient had gained in weight. The pain he regarded as most likely anginal.

A *post-mortem* examination was made, and on opening the thorax the first thing unusual that was noticed was blood in the pericardium. On opening the pericardium, fluid blood at once escaped. The stomach was found to be quite small, and there was no evidence of gastrectasis, but along the lesser curvature was found a hard mass suggestive of malignant disease, but no enlargement of the glands was discovered. The heart and lungs were removed, and given to Professor O'Sullivan for examination. It was evident that death was due to rupture of the heart, which was a very rare cause of death. It was mentioned that Quain had collected 100 cases, of which 77 were of rupture of the left ventricle, and the majority occurred in patients over sixty years of age.

Two points which impressed him were—1st. That hunger pain is not pathognomonic of duodenal ulcer, and 2nd, that steady and progressive increase in weight is not incompatible with malignant disease of the stomach.

Professor A. C. O'Sullivan said the heart showed a rupture, which apparently ran along the anterior wall of the right ventricle close to the septum, and about three-quarters of an inch long. Both ventricles appeared to be ruptured. It was suggested that blood from the left ventricle must have been pumped into the right ventricle when the septum gave way, and immediately afterwards the wall of the right ventricle ruptured. There was extreme fatty infiltration and diffuse fatty degeneration of the heart muscle. The stomach contained a raised mass running from one curvature to the other, which caused thickening of a large area of the stomach wall. Two sections of it were shown under the microscope. There was no ulceration found anywhere. The cancer was of a rather unusual type—small round-celled—and it was only after several sections were made that the cancerous nature of the growth was established. He remarked how seldom one found a state of mental excitement or agitation associated with spontaneous rupture of the heart. He had, however, met with one instance of it.

The President said the condition was a very rare one. George II. died of rupture of the heart at the age of seventy-six. The condition always appeared to be due to fatty degeneration of the heart muscles. He inquired how long the symptoms of rupture were present before the patient died, and if there were endocardial changes at the site of the rupture.

Professor White said it would be of interest to know the number of cases where the rupture was due to diffuse fatty degeneration. He referred to three specimens in the College Museum, in each of which the rupture was due to a localised degeneration of the coronary artery or a branch.

Dr. Parsons, replying, said, with reference to the duration of the symptoms, that when the patient was first seen, as far back as March last, he complained of constricting pains round his stomach, but whether this was to be attributed to the malignant disease of the stomach he was not quite certain. If due to the cardiac degeneration he would date the symptoms back about six months prior to death. With regard to the question as to whether this was to be looked upon as a case of localised degeneration or a diffuse process, he suggested that the specimen showed both.

FAVUS.

Dr. T. T. O'Farrell brought forward this specimen to draw attention to the technique of fixing and staining the hairs for spores and mycelial threads in cases of ringworm and favus.

He used a Gram-Weigert method, and placed the various solutions in successive drops on a white tile. This simplified the process, and rendered the recovery of the hairs an easy matter. The results were excellent.

GLIOMA OF THE FOURTH VENTRICLE.

Dr. T. T. O'Farrell said the specimen was taken from a patient, æt. twenty-four, who was occupied as a labourer in a malthouse. Up to five weeks previous to being seen the man was in good health. It was then noticed that when stooping he was inclined to fall forward. On examination, Romberg's sign was present. Pulse and respirations were normal; temperature sub-normal. Within a week after his first examination the patient came into hospital. When walking to hospital he got a fainting fit. His pulse was weak; he spoke clearly. About twelve hours after admission his speech thickened, and he became stupid. He complained of headache, and his face dropped on the left side. The paralysis extended, and he died about five hours afterwards. At the *post-mortem* examination the brain was examined for hæmorrhage, but none could be found in either side until what appeared to be a large clot was discovered in the fourth ventricle. The conclusion was formed that it was a hæmorrhage into a tumour. Sections showed it to be undoubtedly a glioma. The position was of interest.

The President said that it was obvious that an exact clinical diagnosis would have been extremely difficult as the patient was able to walk about up to a comparatively short time before death.

NOTE ON THREE FATAL CASES OF PHARYNGITIS (with specimen).

Dr. Boxwell read a note on three cases of fatal pharyngitis which had occurred during the scarlatina epidemic in September of this year.

The first two cases showed the intimate relation between scarlatina anginosa and diphtheria. Streptococci were at work in all three cases, but how far diphtheria was responsible for the death in the first case it was impossible to say. In Case II. the recovery of diphtheria from the blood was unusual and interesting. The third case was probably a pure streptococcal septicæmia. Unlike the other two, the temperature ran a very high course—over 105°—almost continuously throughout the illness. A vaccine was made from the pus, but the child was dead before a dose could be administered.

DILATED STOMACH.

Dr. Boxwell also showed a case of obstructive dilatation of the stomach. Owing to the absence of jaundice, the presence of free hydrochloric acid, and swarms of sarcinæ, together with the absence of lactic acid and Boas-Oppler bacilli, it was thought at first that the dilatation was merely atonic. After a few days' rest in bed, combined with lavage, strychnine, saline injections, and a selected diet, the tone of the stomach recovered, and peristalsis became visible through the abdominal wall. On gentle massage, a tumour appeared in the right hypochondrium, which subsided with a gurgle, as though discharging through a narrow opening. It was now clear that there was organic obstruction of some sort, but the patient was too weak for any attempt at operation. She gradually became comatose, and died fourteen days after admission. At the autopsy a small scirrhous cancer of the head of the pancreas was found causing partial obstruction of the duodenum.

NEW LONDON DERMATOLOGICAL SOCIETY.

Meeting held Thursday, November 13th, 1913.

The President, Dr. David Walsh, in the Chair.

Mr. Dennis Vinrace showed a man, æt. 25, with large, symmetrical, pigmented patches, of some two years' duration, on the inner side of both feet. Three months ago lichen planus hypertrophicus was diagnosed, though the thickening had now disappeared.

Dr. Eddowes held the view of lichen simplex, ascribing the pigmentation very possibly to arsenic internally.

Mr. Vinrace replied that squill and digitalis had been given, but that he knew of no evidence of arsenic.

Mr. Dennis Vinrace showed a man, æt. 32, a gardener, with a dry, branny and crusted rash on both hands and forearms. The onset, three months ago, had been sudden, numerous bullæ and a raw discharging surface occurring universally from the elbows to the finger-tips. His circulation was feeble and the hands dusky. There had been progressive improvement following absence from work and mild applications of calamine and plumb. acet.

Dr. Walsh pointed out that the cardiac dulness was one inch outside the nipple line, and that there was a systolic apical murmur and thrill. He had paid a good deal of attention to plant rashes, especially those due to daffodils, or the so-called "lily" rash. In all cases which he had had an opportunity of examining within the past two years he had found some serious defect in the circulation, usually a valvular lesion of the heart. Under certain more or less obscure conditions the juices of most plants seemed able to cause a dermatitis, especially when there was any preceding damage to the skin. There was the well-known *primula obconica*, and he himself years ago had recorded a case due to contact with *angelica*, cut by a confectioner and laid across his bare arms. In Mr. Vinrace's case there was no clue to the precise plant at fault, but there was the predisposing cause in the defective circulation.

Mr. Dennis Vinrace brought forward a girl, æt. 11 (previously shown), with lupus exanthematicus on the left cheek and tip of the left elbow. Six years ago scarlatina, morbilli and varicella occurred successively and ran their course within a period of three or four months. The rash of the chicken-pox all appeared within a few days, and the sores (multiple lupus) all persisted some two years. With the exception of the two surviving lesions referred to on the cheek and elbow, all the sores healed after a further fifteen months, during which active treatment had been applied individually to the lesions. During the last five months ten applications of CO_2 snow had been made to the cheek and elbow with most beneficial results. The centre of the patch on the cheek had healed, and the circumference, which was ulcerated and discharging, was now dry and much improved under the snow.

Dr. Eddowes hoped the case would be shown again in a few months' time, when it would be very interesting to note whether the snow had destroyed the tubercular organisms.

Dr. Sequeira showed a case of cicatricial alopecia following X-ray treatment for ringworm five years ago, done at a school in the East End of London. The scalp was covered with a number of small closely-set patches of baldness, apparently permanent. The case was not seen by him till recently, and he had therefore no opportunity of verifying the original diagnosis.

Dr. Walsh pointed out that the look of the head resembled syphilitic alopecia areata, the numerous small patches giving the well-known moth-eaten appearance. The depressed bridge and general facies of the child to some extent bore out that view.

Dr. Samuel suggested that it may have been a case of favus.

Dr. Eddowes suggested the use of ointment. The nature of the scar did not, in his opinion, preclude all chance of regrowth of hair. It certainly had not the usual appearance of an X-ray scar.

Dr. Sequeira said the mother stated that the child had never been the same mentally since the X-ray treatment, but had become dull and gone down to a lower standard at school. All the hair was stated to have come out after the X-rays, but not to have grown again on the patches.

Mr. Vinrace asked if X-rays affected single areas only, as would appear.

Dr. Sequeira showed a girl, æt. 10, who had suffered since two years of age from recurrent attacks of herpes in the right cheek. These attacks were associated with nasal catarrh. The same spot on the cheek was always attacked, and the eruption lasted for a few days. There were some enlarged glands under the jaw, and the tonsils were enlarged on the same side as the eruption. Dr. Sequeira suggested following Jonathan Hutchinson's liquor arsenicalis treatment.

Dr. Walsh thought the rash probably originated as a reflex to some morbid nasal condition.

Dr. Eddowes agreed it was probably connected with some morbid condition of the left nostril.

Dr. Samuel asked how the last speaker explained the suggested association.

Mr. Vinrace quoted the case of a young man with recurrent herpes 16 years, which took several days to develop and several to clear up, but the disease disappeared eventually under arsenic.

Dr. McLatchie recalled a case of recurrent herpes on groins, treated with arsenic, in which herpes frontalis and zona developed later.

Dr. Meachen had seen a number of cases in school children. Besnier said it occurred in two places—upon the buttocks and the face. Personally, he always used arsenic. Some patients lost the herpetic tendency at puberty.

Dr. Norman Meachen showed a case of

BROMIDE ERUPTION

on the backs of both legs of a girl of 15. The lesions were symmetrical, scabbed, greenish, and infiltrated. No other parts were affected. The patient had attended the Queen's Square Hospital about ten months for epilepsy. In this case the bromide was essential to the treatment of the nerve trouble, and it became a question which one was to choose between—the epilepsy or the eruption.

Dr. Walsh remarked that there was no really satisfactory treatment of bromide rash, and apart from leaving off the drug little could be done. The condition became serious at times, and indeed might even prove fatal.

Dr. **Samuel** said it had been claimed that by increasing the dose you stimulate the kidneys and get rid of the bromism. In one interesting case a child developed a rash from suckling at the mother's breast.

Mr. T. P. **Beddoes** said sometimes the kidneys were stimulated by large quantities of fluid and by stimulating the skin by pilocarpine; and there were other recognised methods of treatment.

Dr. **Meachen** showed a child, æt. 11, with a chronic condition of the hands due to xerodermia. The mother stated that the skin became dry when the child was one year old; mother and brother have same affection. Patient has roughness of the skin over the shins, and the palms dry, hard and smooth. The hair was thin and scanty.

Dr. **Walsh** said years ago he used thyroid gland in these cases, and that was, he believed, now an established remedy.

Mr. **Vinrace** suggested the use of liquid paraffin internally and externally.

Dr. **Samuel** showed a case of lichen scrofulosorum of twelve months' duration treated with codliver oil externally and internally, as recommended by Hebra. The eruption was dense in its early stages, but has nearly cleared up under treatment. There was a family history of tuberculosis—a sister had been in a sanatorium, but patient had no other signs of the disease.

Dr. **Eddowes** said the case was undoubtedly one of lichen scrofulosorum. The little papules were situated at the sweat pores.

Dr. **Samuel** mentioned that several observers had recently found tubercle bacilli in the lesions. This eruption was sometimes a sequela of tuberculin injections. He did not agree that it was the sweat pores which were affected chiefly, but more often, though not invariably, the hair follicles, which accounted for the grouping which was so frequent a feature of the disease. The eruption was a valuable sign of existing tuberculosis in the system which might otherwise be overlooked.

Dr. **Samuel** showed (2) a case of specific disease. The patient, æt. 24, single, was under treatment for syphilis, and recently developed well-marked pityriasis rosea. It was now of three weeks' duration. The distribution was characteristic, viz., trunk, proximal part of limbs, but attacking face and distal. There was no herald patch, but the way the lesions followed the lines of cleavage was characteristic. The peripheral scale, too, differed from other skin diseases by the collarette having its free margin turned towards the centre. The itching in this disease was a variable factor, and was a sort of converse to what obtains in lichen planus—*i.e.*, in lichen planus it is exceptional not to itch, in pityriasis rosea it is exceptional to itch. The pathology was *sub judice*, but he had so often found pityriasis capitis in this disease, and very frequently it occurs in syphilis, and is not uncommonly associated with urticaria. The statement that one attack immunises from a second is not invariably true, as he had seen recently a case which has had repeated attacks of pityriasis rosea.

(3) A case of molluscum contagiosum in a girl, æt. 10. Dr. Samuel said the disease was no doubt due to an ultra-microscopic organism, just like warts, and is common in birds and domestic canaries, also in fowls. The treatment is perfectly simple and efficient.

(4) A severe case of acne vulgaris that had resisted all forms of treatment, including vaccine, but at length cleared up under X-rays. The patient is 24 years of age.

(5) A case of supposed dermatitis artefacta in a woman of about 40. A finger had been removed, and about a month later several blisters appeared on the back of the hand. The lesion improved under plaster of Paris. The finger was amputated for accident, and a compensation of £15 was paid by the employers. Another claim was to be made.

Dr. **Sequeira** had a very similar case that had gone on for three years. It improved wonderfully under plaster of Paris. Patient was supposed to cause the wounds with dry mustard.

Mr. **Vinrace** said that the other side of the case should be carefully considered. If done deliberately what was the underlying mental condition?

Dr. **Samuel** said that apart from the question of compensation and other material benefits, there always arose this question of hysteria—that is to say, the artefact is simply an external expression of a possible repressed mental complex—according to the Freud school, always of a sexual nature, although he was not of the opinion that sexual repressed complexes are always at the root of the trouble, yet often they are, and this expression is just as real as a hysterical anæsthesia or paralysis, and to his mind needs similar treatment—viz., a psycho-analysis with subsequent suggestion, either waking suggestion or hypnotic suggestion. The one thing to avoid doing in these cases is to tell the patient bluntly that you have seen through the cause of the disease, as it invariably leads to disaster and a change of physician. Cure the patient by all means, but preserve silence as to your suspicions.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held November 20th, 1913.

President Mr. **Robert Jones**, F.R.C.S., in the Chair.

Mr. F. **Jeans** read a note on the

"LANE KINK."

Mr. Jeans could not agree with the theory that this condition was due to the upright position. He had never met with it except in association with appendicitis. Where the ileum was kinked he had found that division of the band of adhesion released the ileum, and the lozenge-shaped space so formed was sutured and reformation of the band was prevented by getting the bowels moved early and keeping them released.

Mr. F. T. **Paul** agreed with Mr. Jeans' view of the causation of the kink, and considered there was no warrant for extensive operations such as had been recommended.

Mr. G. P. **Newbolt** read a note on a case of

APPENDIX ABSCESS,

in which there were continued rigors and high temperatures for some weeks after the abscess had been drained and washed out. A vaccine had been made, the discharge having been found to contain an enterococcus which could not be identified. The patient made a complete recovery, which Mr. Newbolt said no doubt was due to the vaccine.

Dr. **Macalister** read a paper on

INFLUENCES OF THE VENEREAL DISEASES.

Dr. Macalister spoke of the influence of public opinion on morality, citing the changes that have taken place as to the use of alcohol, as to the housing of the poor and the use of the individual cup by some Nonconformist bodies in their Communion service. He went on to speak of the part that Dr. W. Carter and Dr. Birkbeck Nevins both past presidents of the society, had taken in the repeal of the C.D. Acts in 1886. It was proved that these Acts did not lessen the evils they were supposed to remedy. At the same time they caused a lessened sense of responsibility from government recognition of immorality. Dr. Macalister thought that other countries would follow the lead of England in giving up such regulative systems. Army statistics showed that when these regulations were rescinded there was a progressive decrease in disease. Education was making the soldier more moral and temperate. With regard to the general population it seems evident that no substantial decrease in the disease is occurring, and a growing number of diseases which were not formerly considered to be syphilitic in origin are now definitely proved to be due to that infection. Dr. Macalister alluded to the fact that proofs are forthcoming that there are occult forms of syphilis, that the results of the infection are far more widespread than was imagined, and that a considerable number of diseases which were not previously known to be associated with syphilis are due to it, as in some cases of mental deficiency, and of epilepsy. Again, it had been shown that congenital heart disease, some gynæcological conditions, many diplegias and cases of paralysis are due to syphilis. Dr. Macalister was with Dr. F. Wilson investigating cases of fibroid bronchiectasis and finding the spirochæte. General paralysis of the insane had been proved to be syphilitic in origin. Gonorrhœa had been proved to be one of the gravest dangers to which womanhood is subjected.

Dr. Macalister appealed to the medical profession as a whole to lend all their influence to educating the public so that they could understand how these diseases not only brought trouble to individuals, but were interfering with labour, were costing money in the provision for the suffering patients rendered unfit to earn a livelihood, and causing deterioration of the race. He pointed out the difficulties of notification until the public had been sufficiently educated. When that had been effected we could go on to the effective segregation of carriers, certification as to fitness for marriage, and other measures for stamping out the plague.

In the discussion that followed, Dr. Hope said that the history of the Contagious Diseases Acts taught us what to avoid, and he thought that in order to give practical and effective assistance in curing the evil the Society should render every help to the Royal Commission. He proposed that a small committee of the Society should be formed to go into the different points and consider how best to assist the Royal Commission. It was agreed that a committee should be formed with power to add to its numbers. The names proposed were the President (Mr. Robert Jones), the Secretary (Dr. A. Stookes), Dr. Macalister, Dr. Hope, Dr. Buchanan, Dr. E. Nevins, Dr. Barendt, Dr. MacKenna, Professor Beattie and Miss Evans.

ULSTER MEDICAL SOCIETY.

Meeting held in the Medical Institute, College Square North, on Thursday, November 27th, 1913.

The President, Mr. A. B. Mitchell, in the Chair.

A POST-GRADUATE DEMONSTRATION OF DISEASES OF THE EAR, NOSE, ETC.

Mr. Craig: (1) A patient from whom a malignant growth of the larynx was removed by thyroid fissure; (2) a patient from whose ethmoid region a large exostosis was removed; (3) a rare case of anterior lenticonus; (4) a patient showing transplantation of skin for severe cicatricial ectropion; (5) peculiar exudates in the fundus following injury; (6) a case of complete loss of iris from injury.

Dr. Davidson: (1) Fœtal remains in an adult of pupillary Membrane; (2) three cases of old iritis showing (*a*) posterior synechiæ, (*b*) pupillary exudate, (*c*) complete occlusion of pupil; (3) double optic neuritis with facial paralysis of cerebral or supranuclear type; (4) retinitis pigmentosa; (5) specific retino-choroiditis; (6) phthisis bulbi—senile ectropion, and malignant disease of fauces, tonsil, and tongue; (7) coloboma of iris and choroid; (8) macula—peculiar condition resembling coloboma; (9) ecchymosis of conjunctivæ and skin of renal origin.

Dr. Killen: (1) Chronic glaucoma; (2) infantile glaucoma; (3) secondary glaucoma with cupped disc (operated); (4) optic atrophy; (5) detachment of retina with extreme myopia, cured by strong saline subconjunctival injections.

Dr. M'Cready: (1) Two cases of traumatic cataract; (2) serpent ulcer, with hypopyon; (3) chronic dacryocystitis; (4) iritis; (5) syphilitic ulceration of throat; (6) lupus of nose and palate.

Mr. Henry Hanna: (1) Phlyctenular disease of the eye; (2) episcleritis; (3) penetrating wound of eye, from which a piece of metal was removed by Haab's giant magnet; (4) carcinoma of the middle ear, under observation for over two years, with results of operations; (5) chronic interstitial keratitis (both eyes), with fundus changes and high myopia; (6) case of adherent leucoma; (7) ulceration of tonsil (malignant); (8) case of iritis; (9) case of iridocyclitis.

Mr. H. H. B. Cunningham: (1) Staphyloma of cornea; (2) keratitis; (3) kerato-irido-cyclitis (two cases); (4) phlyctenular disease; (5) choroiditis.

Dr. Hayden Mulholland: (1) A case of pterygium. (2) marginal blepharitis; (3) trichiasis (result of trachoma); (4) three cases of monocular choroiditis occurring in members of the same family; (5) a case of unusual injury to the eyelid.

SPECIAL REPORTS.

GENERAL MEDICAL COUNCIL.

NINETY-EIGHTH SESSION.

FIRST DAY, TUESDAY, NOVEMBER 25TH, 1913.

The Acting President, Mr. Tomes, in the Chair.

On the suggestion of the Chairman of the Business Committee the Registrar called the roll.

Moved by the Chairman of the Business Committee, seconded by Sir Henry Morris, and agreed to unanimously: "That Mr. Tomes, Senior Treasurer, be requested to take the Chair and to act as President for this day's meeting."

(Mr. Tomes in the Chair.)

The following letter was read from the President:

"University of Glasgow:
"November 17, 1913.

"My Dear Registrar,—As you are aware, I had a sudden and serious illness at the end of October. Though I am now recovering fast, I am not yet strong enough to be out of bed, and my physicians assure me that I shall be unable to go to London next week.

"In the circumstances I must very reluctantly ask the Council to excuse me from duty in the Chair. I have asked Mr. Tomes, as Senior Treasurer, to take my place at the Executive Committee and at the opening of the Session. With your ever-ready help I have endeavoured to arrange the business in a convenient form. The Council will perhaps be willing to forego the usual presidential address for this time.

"Please convey to my colleagues my deep gratitude for the kind and encouraging messages they have sent me, and say that I look forward to a speedy resumption of my active co-operation with them in the work of the Council.

"I am,
"Very truly yours,
"Donald MacAlister."

Moved by Dr. Little, seconded by Dr. Norman Moore, and agreed to with acclamation: "That this Council has received with great regret the President's letter informing them of his serious illness and of his inability to preside at the present session. The Council cannot but feel that the President's unsparing devotion to the duties of his office has contributed to break down his health. The members are rejoiced to hear that he is now making steady progress towards recovery, and they look forward with pleasure to the prospect of having their summer meeting presided over by him, to the great advantage of their proceedings and, as usual, with conspicuous credit to himself."

The following communication from the Victoria University of Manchester was read:—

"The Victoria University of Manchester,
"October 9th, 1913.

"Dear Sir,—I beg to inform you that Professor Lorrain Smith has resigned his post as representative of the University on the General Medical Council, and the University Council have appointed Professor Grafton Elliot Smith, F.R.S., as their representative for a period of two years.

"Yours faithfully,
"Edward Fiddes,
"Registrar.

"The Registrar,
"General Medical Council."

The official notification of the appointment of Grafton Elliot Smith, M.D., as representative of the Victoria University of Manchester for two years from October 8th, 1913, was then read.

Dr. Elliot Smith was introduced by Dr. Norman Moore.

The Acting President called attention to the following resolution, adopted by the Executive Committee, at its meeting on November 24th, 1913, expressing regret at the death of Sir John Tuke. "That the Executive Committee convey to Lady Tuke and the family of the late Sir John Batty Tuke an expression of sincere sympathy at the loss they have sustained by his death, and desire to place on record their high appreciation of his many services to the Council from his appointment in 1887 till his retirement in 1912, and in particular of his devoted labours as Chairman of the Education Committee."

On a motion from the Chair, seconded by Sir John Moore, the Council associated itself with the resolution of the Executive Committee.

Moved by the Chairman of the Business Committee, seconded by Sir Henry Morris, and agreed to: "That the Council do adjourn at 4 p.m. to day to enable certain Committees to meet for the completion of their Reports."

The Council next proceeded to the reception of portraits of

(*a*) Sir William Turner, sent by himself.

The Registrar has received the following from the late President:—

6, Eton Terrace, Edinburgh,
26th September, 1913.

Dear Mr. King,—You will receive a box containing a framed photogravure engraving of a portrait by Sir James Guthrie, P.R.S.A., recently presented to the University of Edinburgh. I ask the General Medical Council to accept it in memory of my long association with it as a member, and for six years as its President.

Believe me,
Faithfully yours,
Wm. Turner.

(*b*) Lord Ilkeston, presented through Dr. Saundby.

Moved by the Chairman of the Business Committee, seconded by Sir Henry Morris, and agreed to: "That a vote of thanks be accorded to Sir William Turner for the photogravure engraving of a portrait of himself by Sir James Guthrie, P.R.S.A., which he has kindly presented to the Council."

Moved by the Chairman of the Business Committee, seconded by Sir Henry Morris, and agreed to: "That a vote of thanks be accorded by the Council to the Dowager Lady Ilkeston and to Dr. Saundby for the portrait of their late esteemed colleague Lord Ilkeston."

Moved by the Chairman of the Business Committee, seconded by Sir Henry Morris, and agreed to: "That the Tables showing the results of competitions for commissions in (*a*) the Naval Medical Service, (*b*) the Royal Army Medical Corps, and (*c*) the Indian Medical Service be received and entered in the Minutes, and be referred to the Examination Committee for its consideration."

Moved by the Chairman of the Examination Committee, seconded by Mr. Hodsdon, and agreed to: "That the thanks of the Council be conveyed to the Director-General of the Medical Department of the Royal Navy, the Director-General of the Medical Department of the Army, and the Under-Secretary of State for India respectively, for the Returns which they have again furnished to the Council, with the request that such returns may in the future continue to be furnished to the General Medical Council."

On the motion of the Chairman of the Business Committee, seconded by Sir Henry Morris, strangers then withdrew, in order that the Council might consider in camera a Report by the Executive Committee in regard to applications for restoration of names after erasure under Section XXIX. of the Medical Act. 1858, and a Report by the Dental Committee in regard to applications for the restoration of names after erasure under Section XIII. of the Dentists Act, 1878.

Strangers having been re-admitted, the President announced that the names of James William Skelley and James Forrest had been restored to the *Medical Register*, and that the names of Frederick Ellis and Edward Joseph Regan had been restored to the *Dentists' Register*.

The Chairman of the Education Committee presented the following Report:—

Report.

The Education Committee reports that as a temporary list of examinations qualifying for admission to the Students' Register applicable to the year 1914 was adopted at last Session, and that as it is not yet possible to arrange this list in its final form, the Committee propose to postpone its Report upon the whole subject until next Session when it will be possible to place all the details before the Council.

John Yule Mackay,
Chairman.

November 25, 1913.

Moved by the Chairman of the Education Committee, seconded by Dr. Norman Moore and agreed to: "That the Report of the Education Committee be received and entered in the minutes."

Moved by Dr. Little, seconded by Sir Charles Ball, and agreed to: "That the following communications from the Irish Branch Council be received and entered in the minutes":—

(*a*)

"Branch Medical Council (Ireland),
"35, Dawson Street,
"Dublin, 20th June, 1913.

"Sir,—The Branch Medical Council meet here today, and, having formed into Committee in accordance with resolution No. 13 (confirmed minutes, 1913, page 36),

"Mr. Robert C. B. Maunsell, F.R.C.S.I., was nominated as Assistant Examiner for the Apothecaries' Hall;

"Dr. John Magee Finny, M.D., was nominated as an Inspector under Sect. 18 of the Medical Act, 1858.

"I have been directed to forward these names to you in accordance with the resolution of Council.

"Your obedient servant,
"James Little,
"Chairman of Committee.

"To the President,
"General Medical Council."

(*b*)

"Branch Medical Council (Ireland),
"35, Dawson Street,
"Dublin, 20th June, 1913.

"Sir,—At a meeting of the Branch Medical Council, held here to-day, Dr. Adye-Curran, on behalf of the Apothecaries' Hall, Dublin, handed me a letter of protest, copy of which I have been directed to forward to you.

"Your obedient servant,
"James Little,
"Chairman, Branch Medical Council.

"To the President,
"General Medical Council."

(*Copy*)

"Apothecaries' Hall of Ireland.
"Mary Street, Dublin, 20th June, 1913.

"Sir,—As representing the Apothecaries' Hall of Ireland I beg to protest against your proposed action of appointing either an Inspector or a Surgical Examiner to act in conjunction with the body which I represent, it being illegal for you to do so, that power alone being vested in the General Medical Council.

"I am, Sir,
"Your obedient servant,
"F. G. Adye-Curran, Lieut-Col., J.P.,
"Representative of the Apothecaries' Hall of Ireland on the General Medical Council.

"The President,
"Irish Branch,
"General Medical Council."

The President, pursuant to the resolution of the

Council of May, 30th, 1913 (Minutes, 1913, pp. 35-36), thereupon appointed Mr. Maunsell :—

"299 Oxford Street,
"London, W.,
"June 27th, 1913.

"In pursuance of a resolution of the General Council of Medical Education and Registration of the United Kingdom, acting under Section 5 of the Medical Act, 1886, Robert C. B. Maunsell (F.R.C.S. Irel.) has been appointed an Examiner in Surgery to assist at the qualifying examinations which are held by the Apothecaries' Hall of Ireland, and to perform the duties specified in the said section or otherwise prescribed under the provisions therein contained.

"The appointment continues for the four years beginning June 21st, 1913.

"Donald MacAlister,
"President."

He also appointed Dr. Finny :—

"299 Oxford Street,
"London, W.,
"June 27th, 1913.

"In pursuance of a resolution of the General Council of Medical Education and Registration of the United Kingdom, acting under Section 18 of the Medical Act, 1858, John Magee Finny, M.D., has been deputed to attend and be present at any of the examinations (other than the examinations in Surgery) required to be gone through in order to obtain the qualification of Licentiate of the Apothecaries' Hall, Dublin, during the year beginning June 21st, 1913.

"Donald MacAlister,
"President."

Dr. Adye-Curran asked a question as to the capacity in which Dr. Finny was deputed to attend the examinations of the Apothecaries' Hall.

The Chairman of the Examinations Committee answered the question by referring Dr. Adye-Curran to the terms of Dr. Finny's appointment by the President.

The Council then adjourned.

SECOND DAY, WEDNESDAY, NOVEMBER 26TH, 1913.

Mr. Tomes in the Chair.

On the suggestion of the Chairman of the Business Committee the Registrar called the roll.

Moved by the Chairman of the Business Committee, seconded by Sir Henry Morris, and agreed to unanimously :—"That Mr. Tomes, the Senior Treasurer, be requested to take the chair for this day's meeting."

(Mr. Tomes in the Chair.)

The minutes of the last meeting were taken as read and confirmed.

The Council proceeded to the consideration adjourned from May 28th, 1913, of the case of Alfred Benson, registered as of 79 Maida Vale, W., M.R.C.S. Eng. 1880, M.B.U.Oxfd. 1880, who had been summoned to appear before the Council on the following charge :—"That being a registered medical practitioner you were on January 8th, 1913, convicted at the Central Criminal Court on your own confession of the following misdemeanour—namely, of having unlawfully, falsely, knowingly, and deceitfully put forward and represented that certain declarations made by you upon forms of application for passports for certain persons named Louis Kiseneyder and Lucas Küschneyder respectively were true ; for which offences you were fined £50."

At the conclusion of the proceedings on May 28th, 1913, the President announced the decision of the Council as follows :—

Mr. Alfred Benson, I have to inform you that the Council has found your conviction proved ; that the Council takes a very serious view indeed of the gravity of the offence of which you have been convicted, and that it has already marked its sense of the gravity of such offences by issuing in the medical journals and elsewhere in November, 1911, a warning notice as follows :—

"Whereas registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give certificates signed by them in their professional capacity, for subsequent use either in Courts of Justice or for administrative purposes. And whereas such certificates include, amongst others :—

"Certificates : (*a*) Under any Statute relating to births, deaths or disposal of the dead ; (*b*) under the Lunacy Acts ; (*c*) under the Vaccination Acts ; (*d*) under the Factory Acts ; (*e*) in relation to children or to excusing school attendance ; (*f*) in connection with sick benefit, insurance and friendly societies ; (*g*) in connection with workmen's compensation ; (*h*) in connection with naval or merchant shipping ; (*i*) for procuring the issue of Foreign Office passports ; (*j*) for excusing attendance in Courts of Justice, in the public services, in public offices, or at ordinary employments.

"And whereas it has been made to appear to the General Council from time to time that some registered medical practitioners have given and signed untrue, misleading, or improper certificates of the above specified or other descriptions. Now, therefore, the General Medical Council hereby give notice that any registered medical practitioner who shall be shown to have given any untrue, misleading, or improper certificate, whether relating to the several matters above specified or otherwise, is liable to be adjudged by them to be guilty of 'infamous conduct in a professional respect' and to have his name erased from the *Medical Register* under Section 29 of the Medical Act, 1858."

In order to give you an opportunity to prove to the Council that you realise the gravity of your offence, and to produce evidence from your professional brethren regarding your character and conduct generally, the Council has postponed judgment till the the November Session, when you will be required to produce testimony to the effect above specified, and to your conduct in the interval.

Mr. Benson attended in answer to his notice. He was not accompanied by counsel or solicitor. He tendered testimonials as to his character and conduct generally and in the interval from Sir David Ferrier, M.D., Sir Malcolm Morris, Mr. James Ernest Lane, and Dr. W. H. Willcox. Leave was accorded to Mr. Benson to put in a further testimonial from the Rev. Alfred R. With, M.A., of the Maida Vale School, which had been received too late to comply with the Orders.

Mr. Harper, acting in the absence of a complainant, read Mr. With's letter, and did not desire to place any fresh facts before the Council.

The Council then deliberated on the case *in camerâ*. Strangers having been re-admitted, the Chairman announced the judgment of the Council as follows :—Mr. Alfred Benson, I have to inform you that the Council does not see fit to direct the Registrar to erase your name from the *Medical Register*.

The Counsel considered the case of James Morrison Orr, registered as of Beulah Grove, West Croydon, M.D., R.U.Irel., 1882, who had been summoned to appear before the Council on the following charge :—

"That being a registered medical practitioner you have knowingly associated in practice with an unqualified and unregistered person—namely, one Horatio Franklyn Sparling, and have knowingly authorised or allowed the said Horatio Franklyn Sparling to exhibit a plate at 30 Northcote Road, West Croydon, with the inscription of 'Dr. H. F. Sparling' thereon above a plate bearing your name, and have thereby enabled the said Horatio Franklyn Sparling to attend and treat patients as if he were duly qualified and registered. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Medical Defence Union.

Mr. Orr attended in answer to his notice, accompanied by Mr. J. W. Marten, of Messrs. Edridge, Son and Marten, of Croydon, his solicitor. The Medical Defence Union, the complainants, were represented by Mr. W. E. Hempson, their solicitor.

The Council's Solicitor having read the notice, Mr. Hempson laid the facts of the case before the Council on behalf of the complainants. He called Mr. Horatio

Franklyn Sparling as a witness and examined him as to the truth of his declaration and as to the writing on two notification certificates which he put in. Mr. Hempson interposed to ask whether the Council desired him to retain two witnesses as to the accuracy of the transcript of the shorthand writers' notes of the proceedings at the inquest on Harry Stephen Eldridge. Mr. Marten accepted them as accurate, and the witnesses were permitted to withdraw. Mr. Sparling was cross-examined by Mr. Marten and re-examined by Mr. Hempson. He answered questions put to him, through the Chair, by members of the Council, and by the Legal Assessor. Mr. Hempson called Mr. Horatio Osmond Sparling as a witness and examined him as to the truth of his declaration. Mr. Sparling was cross-examined by Mr. Marten. Mr. Hempson did not desire to re-examine Mr. Sparling. This closed the case for the complainants.

Mr. Marten opened the case for Dr. Orr, and examined him as to the accuracy of his statement in answer to his notice. Mr. Orr was cross-examined by Mr. Hempson, and re-examined by Mr. Marten.

Mr. Marten then addressed the Council on behalf of Mr. Orr.

On motion by the Chairman of the Business Committee, Clause 1, Cap. IV., of the Standing Orders was suspended, and the Council agreed to sit till 6.30 p.m., or such earlier time as the case might be finished.

Mr. Marten having finished his address, Mr. Hempson stated that he did not wish to address the Council in reply.

Strangers, by direction from the Chair, withdrew in order that the Council might deliberate on the case *in camerâ*. Strangers having been re-admitted, the Chairman announced the judgment of the Council as follows:—

Mr. Orr, I have to announce to you that the Council have found the facts alleged against you in the notice of inquiry to have been proved, and have directed the Registrar to erase from the *Medical Register* the name of James Morrison Orr.

The Council then adjourned.

THIRD DAY, THURSDAY, NOVEMBER 27TH, 1913.

The Acting President, Mr. Tomes, in the Chair.

On the suggestion of the Chairman of the Business Committee, the Registrar called the roll.

Moved by the Chairman of the Business Committee, seconded by Sir Henry Morris, and agreed to unanimously:—

"That Mr. Tomes, the Senior Treasurer, be requested to take the chair and to act as President for this day's meeting."

(Mr. Tomes in the Chair.)

The Chairman of the Business Committee called attention to a report in *The Times* newspaper of the proceedings in the case of Mr. Alfred Benson, which was inaccurate in regard to the account of the announcement from the Chair of the judgment of the Council in the case, the terms used being those employed in the Standing Orders, and as they appeared in the minutes.

The minutes of the last meeting were then taken as read, and confirmed.

The Acting President read the following message from the President:

"I am deeply touched by the terms of the Council's resolution of November 25th, and send my sincere thanks for the kindly feeling to which it gives expression The assurance of the Council's sympathetic consideration has already contributed to my restoration to health, and to the possibility of further service."

The Council considered the case of Harry Roberts, registered as of 63, Harford Street, Stepney, E., L.S.A. Lond. 1895, who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner you have given, under the Public Health (Tuberculosis) Regulations, 1911, on Form of Notification A, to the Medical Officer of Health for the Metropolitan Borough of Stepney, notices in the four cases following, namely:—

"Alice Peacock, dated July 31st, 1912.

"Dorothy Phillips (or Philips), dated October 1st, 1912.

"Albert (or Albert Edward) Wright, dated December 25th, 1912; and

"Edward (or William Edward) Hartshorn, dated January 22nd, 1913,

all of which notices were untrue, misleading or improper.

"And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainants were the Stepney Borough Council.

Mr. Roberts attended in answer to his notice. He was not accompanied by counsel or solicitor.

The Stepney Borough Council, the complainants, were represented by Mr. Hart, counsel, instructed by Mr. G. H. Young, solicitor.

The Council's solicitor having read the notice, Mr. Hart laid the facts of the case before the Council on behalf of the complainants.

He read the statutory declarations of Mrs. Sarah Peacock, Mrs. Mary Phillips, Mr. Edwin Greaves Fearnsides, M.B., M.R.C.P., and Mr. Herbert Simpson, which he put in together with the original certificates and notifications.

He called Mr. D. L. Thomas, M.R.C.S., L.R.C.P., D.P.H., etc., Medical Officer of Health of the borough of Stepney, as a witness and examined him. Mr. Thomas was cross-examined by Mr. Roberts, and re-examined by Mr. Hart. He also answered questions put to him by a member of the Council through the Chair, and by the Legal Assessor.

Mr. Hart called Mr. T. J. Evans, the Chairman of the Health Committee of the Stepney Borough Council at the time the four cases occurred, and examined him as a witness. Mr. Evans was cross-examined by Mr. Roberts and re-examined by Mr. Hart. He answered questions put to him, through the Chair, by a member of the Council.

This closed the case for the complainants. Mr. Roberts then read his statement in answer to his notice, and statements by Mrs. Peacock, Charlotte Peacock, Mrs. M. Phillips, Mr. H. Draper, J.P., Chairman of the Mile End Board of Guardians, and Mr Edwin H. Kerwin, J.P.

He tendered himself as a witness and was cross-examined by Mr. Hart. He also answered questions put to him through the Chair, by members of the Council.

This closed the case.

The Council deliberated on the case *in camerâ*.

Strangers having been re-admitted, the Acting President announced the judgment of the Council as follows:—

Mr. Roberts: I have to announce to you that the Council does not see fit to direct the Registrar to erase from the *Medical Register* the name of Harry Roberts.

The Council considered the case of Thomas Edwin Roche, registered as of 24, Eden Street, Kingston-on-Thames, L.R.C.P. Edin. 1892, L.F.P.S. Glasg. 1892, who had been summoned to appear before the Council on the following charge:—

"That you abused your position as a medical man by committing adultery with a Mrs. Stuart, whom and whose husband you had been attending professionally, of which adultery you were found guilty by the decree of the Probate, Divorce and Admiralty Division (Divorce) of the High Court of Justice, dated March 4th, 1913, and made absolute on September 17th, 1913, in the case of Stuart *v.* Stuart and Roche, in which you were the co-respondent.

"And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The case was officially brought before the Council by the officials of the High Court.

Mr. Roche attended in answer to his notice, accompanied by Mr. John Percival Hope, solicitor, Cardiff.

The Registrar read the notice.

In the absence of a complainant the Council's solicitor laid the facts before the Council. He first asked permission to amend the notice by inserting after "husband" the words "and household," so that the charge would read:—

"That you abused your position as a medical man by committing adultery with a Mrs. Stuart, whom and whose husband and household you had been attending professionally. . . .

"And that in relation thereto you had been guilty of infamous conduct in a professional respect."

Mr. Hope did not take exception to the amendment of the notice.

The Council's solicitor then called Mr. John Dudley Stuart as a witness, and examined him as to the truth of his declaration. Mr. Stuart was cross-examined by Mr. HOPE.

[On motion by the CHAIRMAN of the Business Committee, Clause 1, Cap. IV. of the Standing Orders was suspended, and the Council agreed to sit until 6.30 p.m.]

The Council's solicitor re-examined Mr. Stuart, who also answered questions put to him by the Legal Assessor and by a member of the Council through the Chair.

On concluding his evidence, Mr. STUART made an appeal to the Council on behalf of Mr. Roche.

The Council's solicitor called Mrs. Roche as a witness and examined her as to the truth of her declaration.

Half-past six having arrived, the Council adjourned.

FOURTH DAY, FRIDAY, NOVEMBER 28TH, 1913.

The Acting-President, Mr. TOMES, in the Chair.

On the suggestion of the CHAIRMAN of the Business Committee, the REGISTRAR called the roll.

Moved by the CHAIRMAN of the Business Committee, seconded by Sir HENRY MORRIS, and agreed to unanimously:—"That Mr. Tomes, the Senior Treasurer, be requested to take the chair and to act as President for this day's meeting."

(Mr. Tomes in the Chair.)

The minutes of the last meeting were taken as read and confirmed.

The ACTING-PRESIDENT asked leave to vary the order of business, and to postpone the resumed hearing of the case of Mr. T. F. Roche till four o'clock p.m., to enable a witness whose examination-in-chief had been commenced yesterday to attend for cross-examination, and also to enable the Council's Legal Assessor, who could not attend before that time, to be present.

Leave was accorded.

Moved by the CHAIRMAN of the Business Committee, seconded by Dr. NORMAN WALKER, and agreed to:—"That the report of the Examination Committee on the communication furnished by the Apothecaries' Hall of Ireland in reply to the resolution of the Council (minutes 1913, 94 (6)) be received and entered in the minutes."

Moved by Dr. NORMAN MOORE, seconded by Mr. HODSDON, and agreed to:—That the following report by the Executive Committee be received and entered in the minues:—Report: The Executive Committee calls the attention of the Council to the correspondence with the Privy Council in regard to the Apothecaries' Hall of Ireland, set forth in the minutes of the Executive Committee of Monday, November 24th, 1913. The petition of the Apothecaries' Hall of Ireland, dated July 7th, 1913, has not been entertained by the Privy Council."

Moved by the CHAIRMAN of the Examination Committee, seconded by Dr. NORMAN WALKER: "That the recommendation of the Examination Committee—viz., 'That the Medical Council direct the Registrar to transmit the above report to his Majesty's Most Honourable Privy Council for their Lordships' information,' be adoped."

After a long discussion an amendment was moved by Dr. ADYE-CURRAN, seconded by the CHAIRMAN of the Examination Committee: "That the question of the legality of the appointment and payment of Dr. Finny be referred to the Legal Advisers of the Council." The amendment was not carried.

On the motion of Dr. ADYE-CURRAN, the names and numbers of those who voted for and against the amendment were taken down, and found to be as follows:—Against 17; for, 8; did not vote, 8; absent, 5. The original motion was then put and carried.

On the requisition of Sir CHARLES BALL, the names and numbers of those who voted for and against the motion were taken down and found to be as follows:—For, 26; against, 2; did not vote, 4; absent, 6.

Moved by the CHAIRMAN of the Examination Committee, seconded by Dr. NORMAN WALKER, and agreed to: "That the report by the examination Committee on the final examinations (July and October) of the Apothecaries' Hall be received and entered in the minutes."

Moved by the CHAIRMAN of the Examination Committee, seconded by Dr. NORMAN WALKER, and agreed to: "That the report of the Examination Committee on the Returns from the Services be received and entered in the minutes."

Moved by the CHAIRMAN of the Examination Committee, seconded by Dr. NORMAN WALKER, and agreed to: "That the report by the Examination Committee on the exemptions granted by British licensing bodies be received and entered in the minutes.

Moved by Dr. NORMAN MOORE, seconded by Dr. LATIMER, and agreed to: "That the nomination of the English Branch Council of Mr. Verrall as a member of the Public Health Committee, in the place of Dr. Lorrain Smith, be adopted."

Moved by the CHAIRMAN of the Business Committee, seconded by Dr. BARRS, and agreed to: "That the following report from the Pharmacopœia Committee be received and entered in the minutes:—'The Pharmacopœia Committee report to the Council as follows: —From May 26th, 1913, to Nov. 18th, 1913, the number of copies of the *British Pharmacopœia* (1898) sold by the publishers was 569. The total number of copies sold in the year beginning November 23rd, 1912, was 978. Up to the present time 45,598 copies of the *Pharmacopœia*, and 4,522 copies of the *Indian and Colonial Addendum* have been sold. Two further sections of the text of the new *Pharmacopœia* have been prepared by the Editors, and have been submitted to the Committee and to the several Committees of Reference. All the sections so prepared have been sent to press, and are at present in type, undegoing revision. It is hoped that the appendix, and the concluding parts of the draft, will be ready for consideration early in the New Year.

Moved by the CHAIRMAN of the Public Health Committee, seconded by Dr. NEWSHOLME, and agreed to: "That the following report from the Public Health Committee be received and entered on the minutes:—

"The Committee had under consideration a formal application which was received from the University of Liverpool asking for the registration of the Degree of Master of Hygiene of that University (M.H.). The Committee was informed by the Dean of the Faculty of Medicine of the University that the curriculum for the Degree of Master of Hygiene extends over two years, and includes all the requirements laid down in the rules of the General Medical Council for diplomas in public health. All the courses of instruction which are required for the diploma in public health are taken by the degree students in the first of their two years' study. In every respect they satisfy the rules of the council.

"The Committee recommend the Council to authorise the registration of the M.H. Degree of the University of Liverpool as a qualification in public health

"The Committee also considered a letter, dated November 8th, 1913, from the Secretary of the Royal Institute of Public Health, asking whether, in the opinion of the General Medical Council, that institute is a 'recognised medical school,' within the meaning of 'rule 3 [or] (2) (i)' of the rules adopted by the Council for diplomas in public health relative to a course of instruction in sanitary law, etc., given by a teacher or teachers in the department of public health of a recognised medical school; and, if not, asking the General Medical Council to add such words to the regulations as will remove any doubt which may arise as to the course or courses of lectures at the Royal Institute of Public Health meeting the requirements of the Council.

"It was suggested that after the words 'medical school' in 'rule 3:—Either (1), (e)' and 'rule 3:—or (2) (i.)' the following, or similar, words should be inserted, 'or in a recognised public health institution.'

"The Committee resolved to ask the Council to allow it to consult the legal adviser on the question of amending the rules for diplomas in public health as suggested, and on the general hearing of such an amendment or amendments."

Moved by Sir John Moore, seconded by Dr. Newsholme, and agreed to:—"That the recommendation of the Public Health Committee be adopted, viz.:—'The Committee recommend the Council to authorise the registration of the M.H. Degree of the University of Liverpool as a qualification in public health.'"

Moved by Sir John Moore, seconded by Dr. Newsholme, and agreed to:—"That leave be accorded to the Public Health Committee to consult the Legal Adviser on the question of amending the rules for diplomas in public health as suggested, and on the general hearing of such an amendment or amendments."

Moved by Dr. Norman Moore, seconded by Dr. Mackay, and agreed to:—"That the report by the Students' Registration Committee be received, entered in the minutes, and approved."

The Council resumed the consideration, adjourned from Thursday, November 27th, of the case of Thomas Francis Roche, registered as of 24, Eden Street, Kingston-on-Thames, L.R.C.P.Edin. 1892, L.R.C.S.Edin. 1892, L.F.P.S.Glasg. 1892.

Mr. Roche attended in answer to his notice, accompanied by Mr. John Percival Hope, his solicitor.

In the absence of a complainant the Council's solicitor laid the facts before the Council. He resumed the examination of Mrs. Roche as to the truth of her declaration. She was cross-examined by Mr. Hope. The Council's solicitor did not desire to re-examine Mrs. Roche, who answered questions put to her by the Legal Assessor and by the Chair. The Council's solicitor put in two letters referred to in the evidence given on the previous day—viz., from Mr. Stuart to Mr. Roche, and Mr. Roche to Mr. Hope. This closed his case.

Mr. Hope then called Mr. Roche as a witness and examined him as to the accuracy of the statement which he sent in answer to his notice. Mr. Roche was cross-examined by the Council's solicitor, and re-examined by Mr. Hope. He put in letters from Major-General H. R. Lee, Mr. Thomas Wallace, Senior Consulting Surgeon of the Cardiff Infirmary, Mr. Ivor V. Downing, solicitor, the Rev. G. H. Jennes, Rector of Wenvoe, the Rev. H. J. Williams, formerly Rector of Dinas Powis, the Rev. Charles M. Schooling, of Surbiton, Miss L. Powell, "Lady-in-Charge" of the Factory Girls' Club, Kingston-on-Thames, and Mr. W. J. Kestell, of the Ynishir Steam Coal Co., in business in Cardiff.

Mr. Roche answered questions put to him by the Legal Assessor and by members of the Council through the Chair.

Mr. Hope called Mrs. Florence Emily Stuart as a witness, and examined her as to the accuracy of her declaration. She was cross-examined by the Council's solicitor and re-examined by Mr. Hope. She answered a question put to her by the Legal Assessor. Mr. Hope called Mr. Arthur Edward Hunter, and examined him as to the accuracy of his declaration. He was cross-examined by the Council's solicitor. Mr. Hope then addressed the Council on behalf of Mr. Roche. The Council's solicitor addressed the Council in reply.

Strangers, by direction from the Chair, withdrew in order that the Council might deliberate on the case *in camerâ*. Strangers having been re-admitted, the Acting-President announced the judgment of the Council as follows:—

Mr. Roche: I have to announce to you that the Council do now judge Thomas Francis Roche to have been guilty of infamous conduct in a professional respect, and do direct the Registrar to erase from the *Medical Register* the name of Thomas Francis Roche.

The Acting-President announced that the Council would meet at 11 a.m. on the following day.

The Council then adjourned.

FIFTH DAY, SATURDAY, NOVEMBER 29th, 1913.

Mr. Tomes was appointed Chairman for this meeting.

The Council considered the case of John Edward Sang, registered as of 330 New Cross Road, London, S.E., L.R.C.P.Edin. 1889, L.R.C.S.Edin. 1889, L.F.P.S.Glasg. 1889, who had been summoned to appear before the Council on the following charge:—

"That being a registered medical practitioner you were at the General Session holden at the Central Criminal Court on September 2nd, 1913, convicted of feloniously and unlawfully using certain means unknown with intent thereby to procure miscarriage and sentenced to twelve months' imprisonment with hard labour."

The name of John Edward Sang was directed to be erased from the *Register*.

The Council then considered under Standing Orders XVI., 2, the case of Ralph Raby, formerly holding the qualifications of M.R.C.S.Eng. 1903, L.R.C.P.Lond. 1903.

Mr. Raby was removed from being a member of the Royal College of Surgeons of England on April 10th, 1913. (Executive Committee Minutes, May 26th, 1913, p. 26.) His licence was withdrawn by the Royal College of Physicians of London on October 30th, 1913. (Executive Committee Minutes, November 24th, 1913, p. 53.)

The Registrar had been informed by both of the Colleges that the qualification had been removed in consequence of the issue of objectionable advertisements and not on the ground of his having adopted any theory of medicine or surgery. (Medical Act, 1858, Sec. 28.)

The Executive Committee recommended that in pursuance of Standing Order XVI., 2, and the powers of the Medical Act., 1858, the Acting-President should put from the Chair a resolution to the effect that Mr. Raby's name be removed from the *Register*.

The Standing Order XVI., 2, read as follows:—"If, under the direction of the Council, all the qualifications of any registered medical practitioner have been erased from the *Medical Register*, then the Council shall, if it thinks fit, by formal resolution put by the President from the Chair, direct the Registrar to remove the name of such practitioner from the *Medical Register*."

The name of Ralph Raby was directed to be removed from the *Register*.

The Council received a report from the National Health Insurance Act Committee, *in camerâ*.

On strangers being re-admitted the Registrar read three letters dealing with objectionable methods of advertising and of canvassing with the object of procuring the enrolment of insured persons as the patients of particular medical practitioners, and with the advisability of calling the special attention of all Insurance Committees, Local Medical Committees and Approved Societies and institutions to the warning notices published by the G.M.C. on June 6th, 1889 and December 1st, 1905, and which are still operative.

Mr. Verrall was asked to see the Insurance Comsioners.

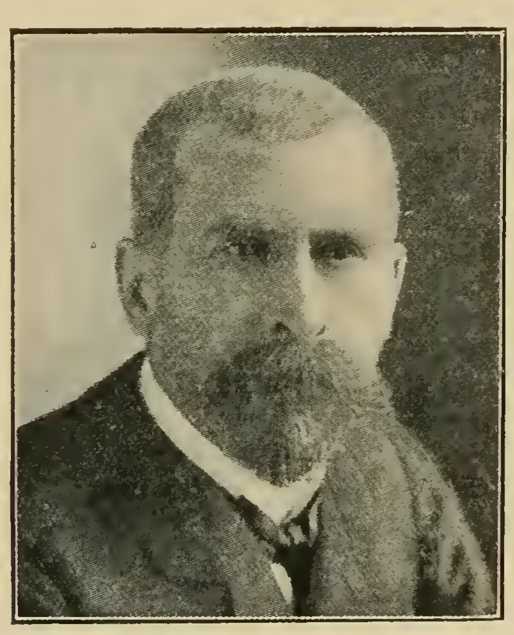
Motion of Sir John Moore, seconded by Mr. Pye Smith, and carried: "To amend the Warning Notice relating to 'Certificates' as follows: (i.) in the preamble to the notice, after the word 'certificates' insert the words 'or notifications or documents of a similar character.' (ii.) In the list of 'Certificates' after (*j*) insert '(*k*) Under the Notification of Infectious Diseases (1889) Act, the Infectious Diseases Prevention Acts of 1890 and 1896, and in regard to the Notification of Tuberculosis.'"

A vote of thanks to the Acting-President was carried by acclamation.

The Council rose.

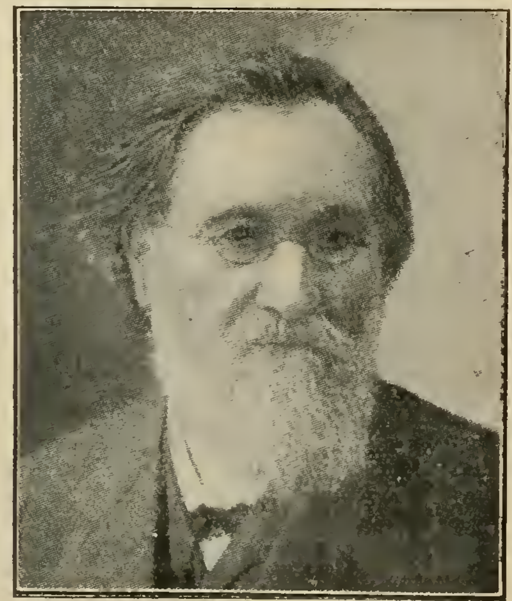
THE TWENTY-FIFTH ANNIVERSARY OF THE PASTEUR INSTITUTE.

A quarter of a century is but a short span in the history of science, though it forms a large portion of the life of an individual. It was on the 14th of November, 1888, that the Pasteur Institute in Paris was opened by President Carnot, and it was appropriate that the twenty-fifth anniversary of this event should have been duly honoured by a commemoration festival in which the present President of the French Republic took part. Through the courtesy of our esteemed contemporary, *Le Paris Médical,* we are enabled to reproduce below the photographs of the two distinguished Directors of the Institute, Professor Roux and Professor Metchnikoff, both men whose names are a household word in medicine.



Professor Roux.

In reviewing the history of the Pasteur Institute, one stands amazed at the immense amount of work and scientific research into the problems of medicine and bacteriology undertaken during the years of its existence, notably in serotherapy, phagocytosis, immunity, arsenical treatment of syphilis, protozoal disorders, sleeping sickness, etc. The science of chemistry as an ally of medicine has taken a large place in the affairs of the Institute, and from its magnificently equipped laboratory there emanates a constant stream of healing for the benefit of the whole world, in the shape of antirabic serum alone. The teaching of bacteriology and hygiene forms another important department of the work of the Institute, and in the latter direction it constitutes the first adviser of the State. True progress in medicine can only be attained by the union of the laboratory with the clinic. The hospital of 80 beds in connection with the Institute, with Dr. Louis Martin as Physician-in-Chief, is an illustration of this axiom. The establishment of research laboratories attached to hospitals or to private clinics, civil or military, throughout the civilised world is an eloquent testimony to the fame of the Pasteur Institute, whose first apostle was our own Lister. For therapeutics to succeed in the fight against disease it must have the support and the collaboration of the clinic as well as those of every science allied to medicine. Thus it has come to pass that the Pasteur Institute has become a veritable medical University.



Professor Metchnikoff.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 29th, 1913.

Colloidal Sulphur.

Prof. Robin advocates the treatment of chronic rheumatism by colloidal sulphur, sulphur being a fundamental element of our tissues. He has treated thus, successfully, several patients affected with rheumatism deformans. One patient who was bedridden for three years from polyarthritis was able to move about at the end of three months. He was not completely cured, it is true, but he could go downstrairs and attend to his little wants.

Colloidal sulphur is, further, one of the best agents against the nocive products of the intestine, rendering them inoffensive.

From time immemorial sulphur has been employed for cutaneous diseases and certain varieties of bronchitis, but the result is perhaps more positive in chronic rheumatism where the tendons and ligaments containing normally sulphur, seem to be deprived of that essential element. The solution, prepared by Dr. Maillard, contains 4 gr. of colloidal sulphur per tablespoon. The initial dose would be a teaspoonful twice a day before meals, but it can be progressively increased to a tablespoonful.

M. Robin employs conjointly moist compresses with lead lotion, massage and progressive mobilisation of the joints.

Treatment of Boils.

The treatment of boils is rendered very simple by the application of tincture of iodine and' ichthyol. Where the boil has suppurated the surface is painted with tincture of iodine and an incision made in the centre of the little tumour. After the pus is evacuated, ichthyol ointment is applied and the parts covered with a suitable dressing. The following day the ichthyol is removed and the surface again painted with iodine, and so on until the secretion has ceased, when the iodine is replaced by pure ichthyol.

Where the boil is hard, and has not yet reached the suppurative stage, the same application of iodine is made and followed by pure ichthyol, which is left to dry (20 minutes); no dressing is required. The next day the ichthyol is removed with soap and hot water and the iodine put on, and so on for two or three days, when the iodine is suppressed and the ichthyol continued for three days more.

Solid Carbonic Acid.

The only difficulty to be encountered in the use of the solid carbonic stick is how to determine the exact duration of the application and the degree of pressure to be exercised, for on these two factors depends the success of the treatment.

In general, one may obtain with from five to ten seconds simple dermatitis; with ten to fifteen seconds, redness, swelling, or even bulla; with twenty to thirty seconds a slight cicatrix is obtained; with from fifty to sixty seconds, large bullæ, sloughing and whitish cicatrix. From ten to thirty seconds would seem to be the limit, in any case it is useless to exceed a minute. A certain degree of pressure is required, for it alone provokes congelation. Young subjects react more readily than adults, fair persons than dark ones.

The chief indications of the treatment are: acne rosacea, superficial angioma, trachoma, corns, chronic eczema, superficial epithelioma, hæmorrhoids. In lupus the carbon pencil can only be an adjuvant to other treatment, as its action is insufficient. For nævi, especially with hairs, the results are excellent; the duration of the application is thirty seconds with moderate pressure.

Fresh patches (small) of psoriasis can be cured in one application. For warts the solid carbon is very effectual, the surface of application should extend a little outside the excrescence.

GERMANY.

Berlin, Nov. 29th, 1913.

At the Society f. Inner Medizin and Kinderkrankheiten, Hr. Kayser showed a case of

Syphilis of the Lungs.

The case was that of a boy, æt. 12, who came under observation on account of complaint of pain in the abdomen and constipation. On examination it was seen that the boy had perforation of the hard palate, and almost complete destruction of the soft palate. On examining the chest infiltration was found in a spot corresponding to the middle lobe of the right lung, the infiltration was confirmed by X-ray examination. The disease was hereditary syphilis from which the child had been suffering from his sixth year. With the exception of the expectoration there were no other outward signs of lung mischief. Anti-syphilitic treatment had been successful in effecting retrogression of all the symptoms.

Hr. A. Fraenkel observed that there were both a gummatous and a fibrinous form of syphilis of the lungs. The case shown was distinctly one of the gummatous kind as the fibrinous form was neither visible by the Röntgen rays nor could it be much influenced by treatment.

Hr. Umber read a paper on

Intermediate Disturbances of Tissue Change.

He said that under normal conditions in the disintegration of albuminous substances introduced into the system in the food there were a number of intermediary "between" products before that of the amino acids was reached. New albuminous products were built up out of these foundation stones. In case of illness due to disturbances of tissue change there were disturbances in the process of disintegration. An insufficiency of disintegration, and a faulty synthesis were possible, and possibly processes that were dependent on anomalies of the internal secretions, for example disease of the hypophyses. An abnormal disintegration of albumen might lead to quite distinct clinical forms of disease. Alcaptonuria and cystinuria were affections that were due to insufficiency of disintegration of albumen. The speaker had repeatedly had the opportunity of studying both forms of disease.

In alcaptonuria, homogentisine and uroleucine acids appeared in the urine. The existence of the latter had repeatedly been called in question, but the speaker had met with a body in the urine in two cases which was certainly not identical with homogentisinic acid. Alcapton urine was, as was known, dark, gave a positive reaction with Trommertes' test and a negative one with Nylander's. Homogentisinic acid gave a transient green colour with chloride of iron. The statements of patients were very characteristic that their linen was stained black in patches. Excretion of homogentisine was dependent on incorporation of albumen. No homogentisine could be found in the blood serum. Ochronosis of the cartilages was very typical of the disease. The nasal cartilage had a blue sheen, the ear cartilage a discoloured appearance, and in consequence of an affection of the cartilages severe osteoarthritis deformans might be set up. Alcaptonuria was therefore by no means a harmless affection. In the cases observed there were also brownish blue flecks on the sclerotic, the tragus of the ear was dark brown, and a green-blue discoloration could be seen under the axilla in the sebaceous glands. The case observed belonged to an alcaptonuric family.

Cystinuria depended essentially on a calculus-forming diathesis. The history of a case was related—that of a man, æt. 42, who came of a strongly diabetic family and suffered from renal colic of the left side. When increased quantities of albumen were given the excretion of cystine also increased. It disappeared also when albumen was withheld from the food.

Hr. Rothmann drew attention to a case of osteitis deformans ochronotica by Sonderberg.

Hr. Hirschfeld related a case of cystinuria in a diabetic in whom after an attack of nephritis no more cystine was observed in the urine.

Hr. Magnus Levy mentioned the case of a cystinuric who was very sensitive to albumen. When it was given to any amount the patient always reacted with fever.

At the Hufelandsche Gesellschaft, Hr. Strauss communicated a note on

Errors of Diagnosis from the Employment of X-Rays.

He said these were due partly to faulty *technique*, and partly to the observer himself. The errors on the part of the observer were mostly in connection with hour-glass stomach, in cases of ulcer of the stomach, which later operation showed had no existence. Spastic hour-glass stomach was a rarity. It might be simulated by the colon being pushed over the stomach. The speaker expressed himself in regard to the frequency of Haudeck's niche. As regarded the appearance of vacuoles in carcinoma they might be simulated by some of the contents of the colon lying in front of the greater curvature.

AUSTRIA.

Vienna, Nov. 29th, 1913.

Radio-therapy of Malignant Growths.

The ever-fertile subject of the treatment of malignant neoplasms has again been the subject of a valuable and interesting communication by Dr. Leopold Freund, who discusses very thoroughly the relative efficiency of radiation treatment and of surgical procedure. He holds a very high opinion of the efficacy of radiotherapy when adopted at an early stage of the development of malignant growths, and strongly advocates its eligibility in the treatment of the same—at a period prior to the evidence of transmission along the lymphatics and blood-vessels, and before any extensive infiltration of the surrounding tissues and organs has become manifest. In cases of very advanced or recurring malignant affection from which extensive infiltration processes have already spread themselves, and where metastatic deposits have formed in distant organs, the therapeutic effect of the radium rays can be calculated on only when emitted from a source so intensive that they can effect the destruction of cancerous tissues after passing through half the thickness of the patient's body. Such a source can, at least from the theoretical viewpoint, effectively deal with all neoplastic growths, when successively applied from opposite sides of the body. In employing so powerful a source of radiation, care must, of course, be taken to filter the rays so effectively that the sifted product can be surely relied on to affect carcinomatous tissues only, without exercising any deleterious effect on the healthy ones. When this conditional postulate can be fulfilled, we can rely upon radio-therapy as an absolutely efficacious curative agent in dealing with malignant neoplasms. But when this condition cannot be attained—as, for instance, when the radiations have but too narrow a range of destructive efficacy—the radio-therapy of cancer can only be regarded as an elegant æsthetic and painless, but, at the same time, merely palliative, method of evacuating foci of cancerous growth—in which the surviving germs will surely produce, after an interval of either short or long duration, a recurrence of the growth; with a progressive development often much more rapid in course, and destructive in character, than the original one had been. The procedure may have a permanently destructive effect on some specimens of malignant growth when adopted at an early stage; also on others which can be quite definitely localised. But the medical man can never positively guarantee a permanently successful result, as he can never be absolutely certain of the extent to which the primary focus has sent out its infiltrating ramifications into the adjacent tissues, or in what proportion its floating germs have passed into the general circulation through the lymphatics and blood-vessels. Even after having secured what appears to be a most happily successful result, he should always hesitate before announcing the achievement of a "perfect cure." Even in parts in which the healing had remained to all appearance perfect for a period of four years after the successful application of the rays, local recurrence has taken place. And even with the complete and permanent healing of a local malignant neoplasm, the object of the practitioner is not attained with the desired certainty. For in some cases in which the application of radiotherapy had a local result which remained permanently perfect, the cancerous disease has appeared, after an interval of years, in parts previously healthy. For instance, mammary carcinoma has appeared in the other breast, Kaposi's sarcoma idiopathicum in other parts of the skin. The previous surgical removal of the pathological tissues must also increase the chances of a successful radiotherapy of internal neoplasms. Thus, it increases the effective results of the application of a weaker preparation, especially when this preliminary treatment has been adopted in an early stage of the morbid growth. It should also be borne in mind in this connection that in deciding what manner of surgical procedure should be adopted in those cases, one should be chosen which will not lead to the formation of thick cicatrices, or the projection of voluminous masses of dense tissue anterior to the original morbid growth. The usual milligramme dosage can have no greater scientific value than this ascribed to it. The radiation dosage to be adopted at each application should be calculated with an eye not only for the quantity of radium employed, and the time limit of the exposure, but also for the quality of the rays with regard to the process of filtration, the superficial and deep limits of the extent of the morbid growth, and the histological and physical characteristics of the latter.

Treatment of Functional Pancreatic Achylia.

Drs. Tibor v. Kern and Emmerich Wiener (of Budapest) have published their clinical experiences of the therapeutic efficacy of pilocarpine and other remedies in the treatment of functional pancreatic achylia. Asthenia with emaciation and diarrhœa, which obstinately resisted ordinary astringent remedies, were prominent symptoms. Their best therapeutic results were obtained from the combined administration of pilocarpine and acidol-pepsin tabloids, which had the effect of controlling the diarrhœa and increasing the body weight.

HUNGARY.

Budapest, Nov. 29th, 1913.

The Differential Diagnosis of Basedow's Disease.

About three years ago Dr. Kraus (Germany) called attention to sudden attacks of intense pain in the upper abdomen and to increased radiation of heat as signs of possibly latent exophthalmic goitre. Dr. Balint, Lecturer to the Budapest University, investigated how far these signs may be regarded as characteristics of Basedow's disease. In two of the most typical of his cases the abdominal pain came on suddenly, resembling gall-stone colic or the crisis of tabes, and was so intense that only large doses of morphine could control it. The iliac plexus was tender, but not the gall-bladder region. The attacks did not correspond to ingestion of food; they came on generally at night, and application of cold or heat gave no relief. The pain was ascribed at first to spasm of the abdominal vessels, and drugs to act on the kidneys were given, but without effect. One patient also had the typical "giving way of the legs" sign of exophthalmic goitre, but there was no paralysis; the extensors of the knees gave way completely all at once, and the patient required aid to get up from the kneeling posture. The very severe acute condition in the other patient had evidently been aggravated by local application of iodine. After exclusion of all other causes for the pain, nothing was left but the assumption of action on the solar plexus of the toxin causing the exophthalmic goitre. In a third case, a man of 28 had suffered for seven years from mild exophthalmic goitre, which was finally aggravated by overwork. Then attacks of pain came on in the night, accompanied by vomiting.

In a fourth case the spasmodic pain was the first symptom of trouble. A man of 52 was suddenly attacked with violent abdominal pain—neuralgia as he supposed. The pain persisted, and he lost 10 kilos in weight in two weeks, and by the end of the month his weight had dropped from 80 to 60 kilos. Several courses of sanatorium treatment brought no relief. By the end of three months symptoms of exophthalmic goitre developed, including restlessness, insomnia, palpitations and pains in the shoulders, but the appetite remained good. On suspicion of "Basedowoid," he was given antithyroidin, and the pains gradually subsided under this and hydrotherapy, with application of the continuous current to the neck. The Basedow triad since has become more pronounced, but the general health has improved and there has been no recurrence of the abdominal pains. Another important sign of hyperfunctioning of the thyroid is the increased radiation of heat from the skin. The temperature in the axilla is liable to be as high as that in the mouth, or even a trifle higher. The burning skin, with otherwise latent exophthalmic goitre may suggest latent tuberculosis. Cardiovascular neurosis may simulate exophthalmic goitre, but the lack of rapid drop of weight speaks against the latter. Hyperthyroidism may induce a condition resembling chlorosis, and during menopause disturbances may develop suggesting the Basedow triad. This borderland disturbance deserves special attention, Balint remarks, as the prevailing tendency to give iodides in prophylaxis or treatment of arterio-sclerosis is liable to induce these nervous disturbances or aggravate a latent tendency of exophthalmic goitre. Another sign of hyperfunctioning of the thyroid is the tendency to frequent and copious stools. This sign is particularly instructive when individuals long constipated suddenly find bowel functioning becoming regular as other signs of hyperfunctioning on the part of the thyroid develop. In all dubious cases the scale is turned by the disproportion between an abundance of nourishing food and the progressive decline in the body weight.

Typhoid Fever in Children.

Dr. Flesch Gustav discusses the points in which typhoid in children differs from that disease in adults. He feeds the child with milk, broth and raw yolks of eggs, with a little wine during the entire febrile stage and convalescence. He thinks the wine is important to keep up the general nutrition. He warns in particular to be on the watch for otitis. The child's heart can be depended on much more than the heart of the adult, and drugs are seldom necessary for disturbances in the heart action, but too much attention cannot be paid to prevention of boils and other disorders of the skin, as secondary septic infection may have most serious results.

Surg.-Lieut.-Col. Henry Walter Kiallmark, M.R.C.S., of The Elms, Ditchling, Sussex, late of the Royal Bucks Hussars and the Army Medical Reserve, and Staff Surgeon to the Ottoman Army, who died on October 23rd, aged 80, left estate of the gross value of £17,156, of which £17,094 is net personalty.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Mileage Grant under the Insurance Act.

Copies of the scheme framed by Commissioners and approved by Treasury for the distribution of the Parliamentary grant in aid of mileage in sparsely populated districts (exclusive of the Highlands and Islands) have now been issued to panel practitioners. The sum of money available for the Lowlands is £16,000. The Commissioners will ascertain the amount of the grant applicable to each county. The basis of the allotment consists in returns received from insurance practitioners, the population and character of the district, and local information furnished by road surveyors, chief constables, and clerks to insurance committees. The Insurance Commissioners believe that they have apportioned the money equitably on these data. The grant is limited to mileage in sparsely populated districts, and account has not been taken of insured persons resident within three miles by land of the nearest insurance practitioner. Special allowance has been made in respect of insured persons whose residence can only be reached by footpath, across moorland or by water. The grants will be made immediately, subject to a balance retained in order that the Commissioners may ascertain how far it is necessary to make allowances for (1) temporary residents, (2) persons becoming insured since April 12th, 1913, (3) geographical and other special difficulties in regard to mileage in any area, and (4) members of the Seaman's National Insurance Society. Under the scheme the Committees shall distribute the grant among the panel practitioners on the basis of one unit for every mile of normal mileage (*i.e.*, distance along a driving road), two and a half units for every mile of special mileage (*i.e.* distance along a road not used for vehicular traffic or across moorland), and four units for every mile of water mileage. In distributing the sum the Insurance Committee may take into account any special circumstances of their area, and vary the scheme accordingly, but the total sum distributed shall not in any area exceed that payable to the Committee by the Commissioners.

Medical Benefit under the Insurance Act.

The immediate distribution of a sum of £17,000 or £18,000 among a body of two or three hundred gentlemen is naturally a subject of lively interest to those immediately concerned, who are anxious to know on what principle or principles the money is to be allocated among them. The Glasgow Insurance Committee has at present this question under consideration of its sub-committee on medical benefit. It is involved in the question of the allocation, among the panel doctors whose lists are not already full enough, of those fifty thousand insured persons who have not made choice of doctors to attend them. When the allocation is made, each practitioner will start with a cash payment as a free bonus, and with his list of insurance patients augmented; it may be doubled, trebled or increased in almost any ratio, so various are the numbers presently on the lists of panel practitioners. It is not to be wondered at that the Insurance Committee have felt some difficulty in fixing the principles on which the allocation is to be carried out. To distribute the unallocated patients among those practitioners who have less than 1,500 on their lists might be unfair to the practitioner who has attracted patients, and in some cases might put a premium or incompetence. On the other hand, some maximum must be fixed; indeed, the error seems to have lain in not fixing a maximum at the beginning—sufficiently generous to allow as free a choice of doctors as possible to all insured persons. To take into consideration—as has been proposed—each doctor's public appointments and present private practice apart from the Act, is scarcely practicable for the Committee. The fairest way would seem to be to allocate those now to be apportioned among the doctors in proportion to their present lists, but so that no list above, say, 2,000, be added to, nor any list be raised above that number.

Glasgow Western Infirmary.

The annual report of the Western Infirmary for the year to October 31st has been issued by the directors. From this it appears that there was a deficiency of £19,305 in the ordinary revenue, and on the basis of this fact the directors make a strong appeal to the public for increased annual contributions. Luckily, on the head of extraordinary income, arising from legacies, donations, etc., there was a balance sufficient to wipe out the above deficiency and to enable the directors to carry £904 12s. to capital account. The number of indoor patients treated during the year was 9,391, and of outdoor 30,935. Of the indoor patients 2,077 were medical, 6,434 surgical, and 318 gynæcological. The infirmary contains about 600 beds, of which 43 have been endowed in perpetuity, mostly in memory of deceased relatives of the persons who have endowed them. At October 31st 700 patients were awaiting admission. In moving the adoption of the report at the annual meeting of qualified contributors on November 27th, Lord Provost Stevenson, who presided, pointed out a gratifying feature in the report—namely, the increase shown in workmen's subscriptions, notwithstanding the Insurance Act. This he took to be an argument in favour of his view that the Infirmaries should be placed upon the rates for support. It showed that compulsory contributions would not, as had been contended, dry up the "fountains of charity." Hospitals were State-supported in France and Germany, where also they had paying wards. Lord Dean of Guild Roxburgh, in speaking afterwards, said that the directors had under consideration the question of introducing paying wards.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

COLOUR DANGERS.

To the Editor of The Medical Press and Circular.

Sir,— In a paragraph on the above subject in The Medical Press and Circular for November 26th, it is stated that for signals at sea and on railways "the colours chosen" (red and green) "are about the worst possible," and that these colours are "the most apt to be confused"; that "about one man in 25 has a deficient colour sense, and by far the most common deficiency is an impaired susceptibility for red."

A series of statements which are so contrary to the facts are seldom seen together, and if the writer finds that he confuses red and green it simply proves that he is colour blind, and cannot consequently be considered capable of giving an opinion on such a subject. It is true that red and green are very apt to be confused by the colour blind, but these colours are by far the least liable to be confused by the normal sighted, and therefore anyone who cannot easily distinguish them ought never to be allowed in a service in which colour signals have to be read. So far from only one man in 25 being deficient in colour sense, the real numbers are from 20 to 25 per cent. who are below normal standard, but comparatively few of them have an error which would allow them to mistake red for green, or the reverse, and so their error is of no practical significance.

The crowning point is reached, however, when the writer states that "blue and yellow would be much more suitable colours from every point of view," and he asks whether "it is beyond the limits of possibility that they will be adopted." I can only say that I trust it is beyond those limits. Does he not know that the masthead lights and the stern lights of all ships under way are "bright" (that is yellow), and that every ship at anchor has a "bright" light on her forestay? Owing, however, to their position, these lights are always easily distinguishable. Does he not remember that all cabin and deck lights are "bright"? If now a "bright" light be substituted for the port or red light, how does he expect the much harassed mariner to distinguish it from the crowd of "bright" lights which renders the modern liner at night precisely like a floating hotel? Has he ever considered the fact that in a fog the first rays to be cut off are the violet and blue? A red light is visible in a fog dense enough to have rendered a blue light invisible at about a quarter the distance, and the very last rays to be cut off are the red ones. To realise this one has only to look at the sun on a foggy day to see that it is the red rays only which can get through, and that the sun and all lights which have any red rays in them will become red before they disappear as the fog gets thicker and thicker, until at last these also are lost. Yellow rays penetrate the next best, and green the next, and these three colours are those which are almost universally used for signals. It is a well-known fact that the electric arc light does not penetrate well in a fog, for in spite of its intense brilliancy it is deficient in red rays compared with the yellow-coloured flame of gas or oil, and for this reason, among others, it is not so universally adopted for lighthouses as it otherwise would be. Accidents at sea happen all too frequently as it is, but there is no need to make things worse by getting rid of red and green lights, which no person with normal vision could possibly confuse or mistake.

I am, Sir, yours truly,
C. Devereux Marshall.

Harley Street, London, W.
November 29th, 1913.

MEDICAL MEN AND LAY PRESS NOTICES.

To the Editor of The Medical Press and Circular.

Sir,—Could you spare a few lines of your valuable space to allow me to direct the attention of your readers to the following from to-day's *Daily News* with reference to the illness of Miss Elizabeth Asquith :—

"The operation was arranged for yesterday morning. Sir Watson Cheyne (who had meantime been to Reigate to perform another operation) called at 10 Downing Street against last evening."

I do not suppose for a moment that Sir Watson Cheyne inspired this paragraph, but it has struck me that if similar detailed information had appeared about some ordinary individual like myself the General Medical Council might have wanted to know the reason why.

I am, Sir, yours truly,
M.A., M.D.Cantab.

London.
December 1st, 1913.

[Surely the Press is alone responsible for this sort of rubbish. How is it to be stopped? The General Medical Council would hardly interfere in any sort of Press notice—otherwise the recent manifesto on the Royal Commission might have produced interesting results.—Ed. M.P. and C.]

OBITUARY.

DR. CLEMENT GODSON.

We regret to announce the death of Dr. Clement Godson, of Sharsted Court, Westgate-on-Sea, and formerly of Brook Street, which took place last week at Montagu Mansions, Portman Square, W.

The deceased, who was 68 years of age, was the eldest surviving son of the late Mr. Charles Godson, F.R.C.S. He was educated at King's College School, London, went to Aberdeen University, and entered St. Bartholomew's Hospital. He became M.D.Aberd. in 1874, and he was elected M.R.C.P.Lond. in the same year. Soon afterwards Dr. Godson was appointed to the newly-created office of assistant Physician-accoucheur to St. Bartholomew's Hospital, a position which he held for over sixteen years. He was examiner in obstetrics in the Universities of Aberdeen and Durham, President of the British Gynæcological Society, and he was also consulting physician to the City of London Lying-in Hospital and other institutions, and formerly physician to the Samaritan Free Hospital for Women and Children. He was the author of numerous articles on puerperal diseases and other subjects in "Quain's Dictionary of Medicine."

Dr. Godson was a vice-president of the League of Mercy and Hon. Surgeon-Colonel of the Royal Army Medical Corps, Territorial Branch, and Officer Commanding the 2nd London (City of London) General Hospital (Territorial Force), and the Volunteer Decoration had been conferred upon him. He was a member of the Court of Shipwrights' Company, and of the Junior Carlton Club. He married Alice, the second daughter of the late Rev. Robert Biscoe Tritton, rector of Bognor, by whom he had four sons and four daughters.

REVIEWS OF BOOKS.

RECENT WORKS ON DENTAL SURGERY AND ANÆSTHETICS.

This work (*a*) has been modelled upon the recently revised syllabus of the Royal College of Surgeons (England), which certainly seems free from errors of omission. The need for a competent dentist to have some idea of the general principles of surgery is obvious, and it becomes more and more evident that he should also beware of many disorders not at first sight connected with his special work, and be able to recognise signs and symptoms which may indicate the need for further advice; but a little knowledge of their differential diagnoses and of their treatment will be the sort of knowledge which is proverbially dangerous, and we do not think it should be expected of him. Nor can we understand why a dental student should be required to learn anything at all about dislocation of the shoulder, cut throat, varicose veins, and many of the other conditions specified, although it must be admitted that the difficulty of deciding what may be safely omitted from the curriculum is a considerable one. The authors have as a rule borne well in mind the special requirements of those for whom they write, and the chapters on bacteriology and on oral sepsis are especially good. To the use of antiseptics and the processes of sterilisation only a short allusion is, however, made in the opening chapter, whilst later on the operator is told to sterilise the patient's skin, etc., "in the usual way." Throughout there is a good deal of the scrappy information just deprecated, but for its inclusion the examiners, rather than the authors, may be responsible. For instance, the application of a tourniquet, or even an attempt to remove a foreign body from the nose, on the brief instructions given, can hardly lead to anything but disaster, and one cannot see any good to the dentist or his patients in the former knowing a little—a very little—about treatment of gangrene of the foot, or of a suppuration of a frontal sinus, or of glaucoma.

A few minor errors may be mentioned, as a further edition will no doubt be required. When reference is made to a figure on another page (as on page 3), the number of that page should be given. "Brawny" (page 43) should be "branny," and "down" (page 252, line 6) should be "up." We prefer "tuberculous" to "tubercular," and "fomentated" (page 41) is novel. "A certain" (which generally means an *un*certain) "degree" occurs rather too often, and there are some tautological expressions, such as "separates off" (page 54), "hard bullets" (page 78), "hoarseness of the voice" (page 243). We have looked in vain in the index for "alveolar abscess," "sinus," "sterilisation"; and "frontal sinus" is given as on page 253 instead of 254. The book is very well printed, and on the whole the authors and publishers are to be congratulated.

This small book (*b*) exemplifies still more the difficulties to which we have already referred, for the issues involved are constantly serious. As it is said, "a medical man," or preferably a skilled anæsthetist, should unquestionably be engaged for any long or severe dental operation, and therefore we think it would have been better if consideration of anæsthesia

---

(*a*) "Surgery for Dental Students." By G. Percival Mills, M.B., B.S., F.R.C.S., and H. Humphreys, M.B., Ch.B., B.D.S., L.D.S. London: Edward Arnold. 1913. Price 12s. 6d. net.

(*b*) "Dental Anæsthetics." By W. E. Alderson, M.D. With a Section on Analgesia, by J. Bolam, L.D.S. Second edition. Bristol: John Wright and Sons, Ltd. 1912.

in such cases had not been attempted. The accounts of the more dangerous anæsthetics are necessarily so brief as to be of little use (supposing that a dentist should ever administer them) whilst some of the personal opinions expressed may lead to troublesome contentions. We agree, however, that chloroform is particularly dangerous for dental operations, and may add that as surgical shock (unlike psychic shock) is not abolished by full anæsthesia, no severe one should be done in a dentist's room, if other arrangements are possible. The accounts of nitrous oxide as usually given, and of the nasal method, are fairly good, but minor difficulties might be more fully considered. Cardiac failure follows commonly respiratory obstruction, rather than respiratory failure, under such circumstances, and it is important that this should be realised by students. There is no need for a "cumbersome and costly apparatus" for short administrations of nitrous-oxide and oxygen; excellent results can be obtained with a simple one, such as described in Mortimer's "Anæsthesia and Analgesia."

It is difficult to understand the distinction between "stages" and "phases" and the table on page 7, nor have we observed "late coughing and retching of central origin" under ether, nor "breathing without respiring" (except as a result of obstruction).

It is not necessary or convenient to give nitrous-oxide to "near completion" when it is intended to follow on with ether, and the disadvantages of the "asphyxial factor" of the closed method can be more readily avoided than might be inferred from the author's description.

In emergency, laryngotomy should be done as described in Messrs. Mills and Humphreys's book, not deliberately. Cases are unlikely to occur in which more effectual methods than Laborde's cannot be employed, and it might well be omitted. In Sylvester's method "expiration" should be done first.

The section on Analgesia is generally good, as far as it goes, and we are glad to notice that stress is laid upon the dangers of sepsis. It may, however, be remarked that there is risk of much after-pain, and even of sloughing, if inflamed gums are frozen. The student will not find it helpful to be allowed to "use his own discretion" in selecting an analgesic drug. Surely it is time that cocaine should be discarded in dental work? We have criticised this little book at some length, for it is evidently popular, and the subject one of great importance.

VOCAL EXPRESSION. (*a*)

The lifeless manner in which many lectures and sermons are delivered by public speakers and teachers is a sufficient comment upon the scant attention paid to the subject of vocal expression generally. At least, such is the inevitable impression gained by enduring for a solid hour the monotonous delivery of many a well-known academic lecturer. The collection of papers, originally written for a musical journal by an acknowledged authority on voice-training, which form the subject matter of this little work contains much that is of interest to medical readers. The author has the strong conviction that the true development of vocal expression depends upon stimulating and accentuating the processes of thinking and feeling, and in so far as he recognises the value of psychic conditions as influencing bodily function he is quite right. Far too many orators and readers are slaves to mere mechanical rules of elocution, if, indeed, they ever succeed in escaping from the thraldom of dulness. The lecturer who "draws" the biggest audience—provided, of course, that his matter is good—is he who, out of the fulness of his heart, speaks in a conversational style, yet forcibly and convincingly, now appealing to the intellect and, then stirring the emotions of his hearers. All who have to speak in public will benefit from a perusal of this little handbook.

ALIMENTARY ENZYMES. (*a*)

In this book the passage of food through the alimentary tract is well described, special consideration being given to the action of the various enzymes. This is followed by descriptions of the composition of milk, cream, starch and barley water, with short chapters dealing with predigested foods and the feeding of infants. A second part of the book answers various questions that have been raised over the products of Messrs. Benger's Food Co., Ltd. The book is intended for the sole use of medical men, and it is thoroughly deserving of perusal by them. Its *raison d'être* is sound and honest, and the book will rank as another "Benger product" of merit. We may permit ourselves a comment to the effect that milk containing only 0.70 per cent. of ash (which is given as the average figure) will in the large majority of cases contain added water.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

Appleton, D., and Co. (London).
- Manual of Obstetrics. By John Osborn Polak, M.Sc., M.D. Illustrated. Pp. 468. Flexible leather. Price 12s. 6d.
- Minor Medicine. By W. Essex Wynter, M.D., F.R.C.S., etc. New second edition. Revised and enlarged. Pp. 275. Price 6s.

Bailliere, Tindall and Cox (London).
- Treatment by Hypnotism and Suggestion, or Psycho-Therapeutics. By C. Lloyd Tuckey, M.D., Aberd. Sixth edition, illustrated, revised and enlarged. Pp. 431. Price 10s. 6d.
- Radium: Its Physics and Therapeutics. By Dawson Turner, B.A., M.D., etc. etc. Second edition, revised and enlarged. Illustrated. Pp. 170. Price 5s.
- Diseases of Children: A Manual for Students and Practitioners. By John McCaw, M.D., R.U.I., L.R.C.P.Edin., etc. Illustrated. Pp. 524. Price 10s. 6d.

Bale, John, Sons and Danielsson, Ltd. (London).
- The Tuberculosis Year Book and Sanatoria Annual. Edited by T. N. Kelynack, M.D., Vol I., 1913 and 1914. Pp. 476. Price 7s. 6d.

Cambridge University Press (Cambridge).
- The Chemistry of the Leucocytozoon Syphilidis and of the Host's Protecting Cells. By J. E. R. McDonagh and R. L. M. Wallis.

Chapman and Hall (London)
- Handbook on Sanitation. By George M. Price, M.D. Third edition. Pp. 353. Price 6s 6d.

Churchill, J. and A. (London).
- A Short Practice of Midwifery for Nurses. By Henry Jellett, B.A., M.D., F.R.C.P.I. Fourth edition. Revised and illustrated. Pp. 508. Price 7s. 6d.
- A Course of Lectures on Medicine to Nurses. By Herbert E. Cuff, M.D., F.R.C.S. Sixth edition. Pp. 281. Price 3s. 6d.
- The Diseases of Children. By Sir James Frederic Goodhart, Bart., M.D. Tenth edition. Illustrated. Edited and Revised by G. F. Still, M.A., M.D. Pp. 959. Price 16s.
- The Ideals and Organisation of a Medical Society. By Jamieson B. Hurry, M.A., M.D. Pp. 51. Price 2s.

Clarendon Press, The (Oxford).
- Spencer's Philosophy of Science: The Herbert Spencer Lecture Delivered at the Museum, 7th Nov., 1913. Pp. 53. Price 2s.

Dornan, W. J. (Philadelphia).
- Medical and Surgical Reports of the Episcopal Hospital. Vol. I. Pp. 406.

Kelly, Charles H. (London).
- Youth. Edited By T. N. Kelynack, M.D. Pp. 152. Price 1s.

Lewis, H. K. (London).
- Lectures on Medical Electricity to Nurses. An illustrated manual by J. Delpratt Harris, M.D.Durh., M.R.C.S. Pp. 88. Price 2s. 6d.

Leadenhall Press (London).
- The Progress Book. An Illustrated Register of Development from Birth till Coming of Age and After. By J. J. Pilley, Ph.D. Revised and enlarged edition. Pp. 96.

J. B. Lippincott Co. (London).
- International Clinics. A Quarterly edited by H. W. Cattell, A.M., M.D., Philadelphia. Vol. III. Twenty-third series. 1913. Pp. 303.

Livingstone, E. and S. (Edinburgh).
- Materia Medica Notes. By James A. Whitla, L.R.C.P. and S., L.P.S.I. Pp. 157. Price 2s. 6d.

(*a*) "The Art of Vocal Expression." A popular handbook for speakers, singers, teachers and elocutionists. By the Rev. Chas. Gib. Pp. x., 91. London: William Reeves. 1913.

(*a*) Benger's Food, Limited, Manchester. Pp. 108, xviii., with 10 plates. 1913.

London University Press (London).
Mental Diseases. By R. H. Cole, M.D.Lond., M.R.C.P. Illustrated. Pp. 343. Price 10s. 6d.

Longmans, Green and Co. (London).
The Administrative Control of Smallpox: How to Prevent or Stop an Outbreak. By W. McC. Wanklyn, B.A.Cantab., M.R.C.S., L.R.C.P., D.P.H. Pp. 86. Price 3s. 6d.
A Manual of Surgical Treatment. By Sir W. Watson Cheyne, Bart., C.B. and F. F. Burghard, M.S.Lond. New edition, revised and rewritten, with the assistance of T. P. Legg, M.S.Lond., F.R.C.S. and Arthur Edmunds, M.S.Lond., F.R.C.S., in five vols. Vol. V Pp. 619. Price 21.

Macmillan and Co., Ltd. (London).
Feeding and Care of Baby. By F. Truby King, M.B., B.Sc. Pp. 162. Price 1s.

Ophthalmoscope Press, The (London).
Guide to the Microscopic Examination of the Eye. By Prof. R. Greeff with the co-operation of Prof. Stock and Prof. Wintersteiner. Translated from the third German edition. By Hugh Walker, M.A., M.B., C.M. Pp. 86. Price 7s. 6d.

Parke, Davis and Co. (London).
The Treatment of Rheumatic Infections. Pp. 134.

Putnam's, G. P., Sons (London).
Text-Book of Anatomy and Physiology for Nurses. By Amy E. Pope. Illustrated. Pp. 554. Price 6s.

Saunders, W. B., Company (London).
A Clinical Manual of Mental Diseases. By Francis X. Dercum, M.D. Pp. 425. Price 13s.
Illustrated Medical Dictionary. Edited by W. A. Newman Dorland, A.M., M.D. Seventh edition. Revised and enlarged. Pp. 1,107. Price 19s., with thumb index 21s.
The Pocket Medical Dictionary. Edited by W. A. Newman Dorland, A.M., M.D. Eighth edition. Revised and enlarged. Pages 677. Price 5s., with thumb index 6s.

Scientific Press, Ltd., The (London).
The Mutilated Hand and the Workmen's Compensation Act, 1906. By J. J. Scanlan, L.R.C.S. and P.Edin. Pp. 90. Price 2s. 6d.

Wright, John, and Sons, Ltd. (Bristol).
The Biology of Blood-cells. By O. C. Gruner, M.D.Lond. Pp. 392.

Williams and Norgate (London).
Nerves. By David Fraser Harris, M.D., C.M., B.Sc., etc., etc. Pp. 256. Price 1s.

LITERARY NOTES.

Among the many calendars sent us for the coming year is a most artistic reproduction in colours of the celebrated picture in the Louvre Gallery, Paris, of "Madame Le Brun and Child." The colouring is excellent and follows the original as closely as it is possible in colour-printing, the size being about 10 inches by seven. It is issued by Mellin's Food Co., Ltd., Peckham, London, S.E., who state that they are prepared to send a copy free of cost to the readers of this journal on receipt of threepence in stamps to cover the cost of postage.

* * *

Messrs. J. and A. Churchill announce the publication of the following new editions:—The 10th edition of "The Diseases of Children," by Sir James Frederic Goodhart, Bt., M.D., LL.D., F.R.C.P., and George Frederic Still, M.D., F.R.C.P.; the 4th edition of "A Short Practice of Midwifery for Nurses," by Henry Jellett, M.D.Dub., F.R.C.P.I., and the 6th edition of "Lectures on Medicine to Nurses," by Herbert E. Cuff, M.D., F.R.C.S.

* * *

Messrs. Bailliere, Tindall and Cox announce for publication Bulkley's "Diet and Hygiene in Diseases of the Skin," Findley's "Treatise of the Diseases of Women," McCaw's "Diseases of Children," Morison's "Sensory and Motor Disorders of the Heart," Tuckey's "Treatment by Hypnotism and Suggestion," 6th edition, Dawson Turner's "Radium," crown 8vo, 2nd edition. Curiously enough, this latter is the only medical book of English origin on the subject in the study of which Dr. Dawson Turner is so well known. Simon's "Clinical Infection and Immunity," 2nd edition (with coloured plates). The first edition of this latter book was disposed of in a few months, which undoubtedly proclaims it a work of great merit. It includes chapters on Serum Therapy, Vaccine Therapy, Chemotherapy and Serum Diagnosis.

* * *

The special Christmas number of *Truth* is crammed with good things. The satirical poems entitled "St. George and the Dragon" and "Forcible Feeding," respectively, illustrated by coloured plates and cartoons, will appeal to medical men by their topical humour, notably the one depicting "A Strike of Leeches," in which many eminent members of the profession appear in hirudinous disguise. Altogether this number is essentially one for the waiting-room table as well as for the fireside, and it should on no account be missed.

* * *

The "Deaf Handbook" (London P. S. King and Son) is an unpretentious little brochure which has been compiled by the National Bureau for promoting the general welfare of the deaf, and contains a variety of information of much value. It may be said to be a directory of the many and varied organisations dealing with that class from childhood to adult life. There is a short account of the Acts of Parliament affecting the deaf. Any medical man called in consultation regarding a deaf person would be well advised to look to this book for guidance.

* * *

The most interesting and to a certain extent the most instructive biographical notice we have read of Lord Lister is in the November issue of the *Sunday at Home*, entitled "The Religion of a Man of Science," by Allan Green. Lister did not parade his religion in the arena of controversy, says the writer. "That which suffused his personality was not to be trafficked with in argument, as though it were on a plane with his advocacy of the germ theory, or the use of carbolic acid in wounds. His was a spontaneous piety, like that of Lord Kelvin, who was to physics what Lister was to surgery. With both men their religion was something which shimmered behind the spoken and written word." No wonder that many of Lister's students in Edinburgh confessed that their contact with him was the best and purest influence of their lives.

LABORATORY REPORTS.

DIA-PARAFFIN.

This new preparation contains the well-known brand of malt extract and liquid paraffin, the latter being present to the extent of 28.72 per cent. according to our analysis. The preparation is a powder of a slightly crystalline appearance and a light buff colour. It has a pleasant slight odour of malt, and in taste it very closely resembles pure extract of malt. The taste is entirely devoid of any suggestion of oil. Dia-paraffin, when added to water, quickly forms a pale buff-coloured emulsion, which is quite stable. We administered the powder to two subjects who would be nauseated at the thought of taking oil. Both enjoyed it and experienced no stomachic unpleasantness. The usefulness of liquid paraffin is too well known to require emphasis here, but the effort generally needed to take it very greatly diminishes its scope. Hence we welcome this very admirable and entirely successful attempt to render the oil not only palatable, but actually attractive. We may add that the preparation is made for the Saccharin Corporation, Ltd., 10 Arthur Street, E.C., by the British Diamalt Company.

MEDICAL NEWS IN BRIEF.

The London School of Clinical Medicine.

The annual dinner in connection with the London School of Clinical Medicine (post-graduate) attached to the Seamen's Hospital, Greenwich, was held last week at Princes' Restaurant. Surgeon-General A. W. May, C.B., R.N. (Medical Director-General of the Navy), presided, and among those present were Sir Archibald Geikie (President of the Royal Society), Sir Thomas Barlow (President of the Royal College of Physicians), Sir Dyce Duckworth, Sir F. H. Champneys, Sir Havelock Charles, Admiral Sir J. Durnford, Sir James Chrichton-Browne, Sir J. Rose Bradford, Surgeon-General Sir W. L. Gubbins, Surgeon-General Sir James Porter, Commander H.

Bowring, R.N.R., Dr. Frank Heath, Sir Malcolm Morris, Sir William Bennett, Sir J. Mackenzie Davidson, and Mr. C. C. Choyce (the Dean).

The Chairman, in proposing the toast of "The School," said that at the present time they were on the wave, if not at the top of the wave, of an extraordinary advance in medical science. The "Dreadnought" medical college was giving its education and the riches of its accumulated learning to a body of men who were doing great service to the Navy and to the country at large, and it was in addition conferring benefit on the great Service to which they had all the honour to belong—the Navy.

Sir Archibald Geikie, in proposing "The Medical Profession," contrasted the position of medicine in the present day and 300 years ago. Nobody laughed at the doctor now. In all directions medical men had not only advanced their own profession, but they had to a very large extent gone out of their own sphere and advanced other branches of science.

Sir Thomas Barlow and Sir J. Crichton-Browne replied.

The Society of Apothecaries of London.

Mr. Martindale Ward (the Master) presided at a dinner of the Worshipful Society of Apothecaries last week at Apothecaries Hall, and among those present were Mr. Meredith Townsend and Mr. George Amsden (wardens), the presidents of the Medical Society of London, the Pharmaceutical Society, and the Society of Public Analysts, the Masters of the Grocers', the Girdlers', and the Carpenters' Companies, Mr. G. H. Makins, C.B., Sir Thomas Crosby, Sir George Savage, Surgeon-General Jeffcoat, and Dr. Norman Moore.

At a meeting of the Court before the dinner, Sir William H. Power, senior medical officer of the Local Government Board, was formally elected an honorary freeman of the society in recognition of his services to the State in regard to public health, and the Master presented the Society's gold medal to Mr. J. E. Harting in recognition of the assistance which he had given to Mr. W. Bramley Taylor (the late Master) in preparing a catalogue of the society's library.

Panel Doctor's Certificates.

In the City of London Court, last week, a case of importance to all insured persons and panel doctors was heard in which a woman, named Kipps, of Upper Grange Road, Old Kent Road, sued the Prudential Approved Society for Women, Holborn Bars, for 15s., being two weeks' benefit money at 7s. 6d. per week under the National Health Insurance Act.

Plaintiff's counsel said it was a test case. Plaintiff was ill after her confinement, and her panel doctor certified her incapacity. The medical certificate was signed by a rubber stamp, and the defendants had refused to pay the money in consequence. The society, he contended, had no business to adopt that attitude.

Defendants' counsel stated that as the rules provided for arbitration that Court had no jurisdiction. The Insurance Commissioners had issued a pamphlet requesting the doctors to sign their certificates in the ordinary way instead of using a rubber stamp, as it was found that in some cases housemaids had been affixing the rubber stamps to certificates without any authority from the doctors. He cited cases to show that the Court had no jurisdiction, and expressed the hope that the Court would not think the society's objection was capricious.

Judge Rentoul said he was sure it was not. There was no reflection on the society. The sole question was their legal rights. He must hold that the Court had jurisdiction, and that it was not ousted by the National Health Insurance Act. He would find for the plaintiff for the amount claimed, with costs on B scale, and he would give leave to appeal, as the dispute was certainly an important one.

Medical Man Sentenced.

On Monday last at the Manchester Assizes, before Mr. Justice Avory, James Vose, district superintendent of the Britannic Assurance Company (Limited), and Michael Joseph Ryan, medical practitioner, both of whom have been prominently associated with Church work in Bolton, were charged with obtaining various sums of money from the Britannic Assurance Company by making false declarations in regard to alleged death certificates, and with using the same as true, with intent to defraud the company.

Vose was for many years shareholders' auditor for the Bolton Wanderers' Football Club. He pleaded "Guilty," but Ryan, who denied the charges, alleged that he had given the certificates at Vose's instigation in the belief that there was nothing wrong. He said he was entirely innocent of fraud. He had known Vose for many years as a town councillor and churchwarden, and he regarded him as a man of integrity and honour. Vose told him the certificates were for the private use of the company and were not for registration, as the deaths had already been registered.

The Judge: Does it amount to this, that you were prepared to write down any falsehood at the dictation of any churchwarden—Ryan replied that he did not believe Vose would do any wrong or ask anyone else to do wrong.

In answer to further questions, Ryan said he would rather not give the name of the other medical man who, according to Vose, had signed certificates for him, but he was not a man the witness knew, though he had heard of him.

Ryan was convicted and sentenced to six months' hard labour, and Vose was sentenced to 10 months' hard labour.

Medical Man's Will—Big Bequests to Charity.

The late Professor Campbell, M.D., F.R.C.P.I., Hazelwod House, Dundrum, left personal estate valued at £21,314.

He left £10,000 to the Bishop of Meath towards the erection of a Catholic Cathedral in the diocese of Meath, intended to be erected at Mullingar; £5,000 to his brother-in-law, the Rev. David Morrissey, to be applied by him for charitable purposes in Ireland; £2,700 to be divided amongst 15 specified Irish charities; £100 and his household effects to Miss Elizabeth O'Brien, of Frankfort Avenue, Rathgar, and the residue of his estate he left for charitable purposes in Ireland.

University of Cambridge.

At a Congregation held on November 28th the following degree was conferred:—M.D.—H. E. S. Stiven (by proxy), Trinity.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

S. W. (Hendon).—The chemistry of senna leaves has been the subject of many recent investigations, notably by Tsehireh, Hiepe, and F. Tutiar, who have found in addition to rhein, salicylic acid, aloe-emodin, and kaempferol, a new glucoside of the latter substance in an alcoholic extract of the Tinnevelly leaves.

M.B.DURH. (Sussex).—The ordinary impetigo contagiosa is of streptococcal origin, and because this condition is frequently bullous in infants it is often mistaken for true pemphigus neonatorum. When the latter occurs in an epidemic form, as, for instance, in the practice of one particular midwife, it has been found by Drs. Wanklyn and Macrory, by bacteriological examination, to be streptococcal, and, therefore, to be a form of impetigo contagiosa.

MR. R. COLE (Hackney).—The child would be far better taken care of and educated in one of the institutions where lip-reading is made a speciality. It is often very difficult to distinguish between slight mental deficiency and mere backward development, but speech defects can be remedied to a great extent by patient and persevering tuition by a capable teacher.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 3RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE) (1 Wimpole Street, W.).—5 p.m.: Papers by Dr. Raymond Crawfurd: Martial and Medicine. Dr. J. D. Rolleston: Medicine in the Greek Anthology (Part II.). An exhibit will be made of Objects of Medical and Surgical Antiquarian Interest by Mr. C. J. S. Thompson from the Historical Medical Museum of Mr. Henry Wellcome.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8 p.m.: Cases and Specimens by Mr. J. Herbert Parsons. 8.30 p.m.: Papers by Mr. N. Bishop Harman: An Operation to Improve the Effect of an Artificial Eye. Mr. W. M. Beaumont: Iritis, Rheumatic and Toxæmic. Dr. Gordon Holmes and Mr. R. A. Greeves: Sarcoma of Choroid with Extensive Secondary Dessemination.

THURSDAY, DECEMBER 4TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Dr. Guy Hinsdale: Mineral Springs, their Analyses and Newer Methods of Applications, etc., with a Note on Radio-activity of Mineral Waters. (At 7.15 p.m. the Members will dine together at the Welbeck Palace Hotel, Welbeck Street, W. The charge for the dinner is 4s. each, and Members may bring guests. Members who wish to dine are requested to send their names to Dr. J. Campbell McClure, 41 Welbeck Street, W.)

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8 p.m.: Specimens by Mr. Alban Doran, Mr. J. D. Malcolm, Dr. G. G. Alderson, Dr. Wilberforce Smith, and Mr. Gordon Luker. Short Communications by Dr. H. R. Spencer, and Mr. Victor Bonney. Papers by Mr. Beckwith Whitehouse: The Relation of Syphilis to the Uterus. Dr. M. G. Stewart: Case of Fœtus Acardiacus Amorphus.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Meeting.

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.).—7.30 p.m.: Mr. P. B. Ballard: Left-Handedness.

FRIDAY, DECEMBER 5TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4 p.m.: Cases by the President (Dr. D. R. Paterson), Dr. W. Hill, Mr. Layton, Mr. A. J. Wright, Mr. G. Potts, Dr. E. A. Peters, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANÆSTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Paper by Dr. A. Flemming: Review of Inquests concerning Deaths during Anæsthesia 1910-1913.

ROYAL SOCIETY OF MEDICINE (SECTION OF PATHOLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Laboratory Meeting at the Royal Army Medical College, Grosvenor Road, S.W.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8 p.m.: Cases will be shown. 8.30 p.m.: Paper: Mr. J. E. R. McDonagh: The Biology of Syphilis, illustrated by lantern slides, followed by discussion.

MONDAY, DECEMBER 8TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: (1) "A Case of Aneurysm of the Arch of the Aorta, treated by Colt's Method of Wiring. Death four months later" (with specimen). Sir Anthony Bowlby, C.M.G., F.R.C.S., and Mr. D'Arcy Power (2) "Circumcision. The Advantages of a Modified Operation," Mr. T. H. Kellock.

TUESDAY, DECEMBER 9TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF PSYCHIATRY) (Royal Bethlem Hospital, St. George's Fields, S.E.).—4.30 p.m.: Cases: Dr. W. H. Stoddart: (1) Hypopituitarism, (2) (?) Anxiety Neurosis, (3 and 4) Dementia Paranoides, (5) Congenital Neurasthenia, and other Cases.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY).—5.30 p.m.: Papers: Mr. Gilbert Kempe: Brachial Arteriovenous Aneurysm successfully treated by Vascular Suture. Mr. V. Zachary Cope: The Early Diagnosis and Treatment of Ruptured Intestine. Mr. H. Betham Robinson: Case of Endothelioma of the Breast.

Appointments.

BENNETT, J. G., M.B., Ch.B.Vict., Senior House Surgeon at the Manchester Royal Infirmary.

COPLANS, E., M.R.C.S., L.R.C.P.Lond., House Surgeon at Bolingbroke Hospital, Wandsworth Common, S.W.

DAVIES, H. MORRISTON, F.R.C.S.Eng., Honorary Surgeon to the City of London Hospital for Diseases of the Chest, Victoria Park, E.

FURNESS, HAROLD S., M.D., B.S.Lond., House Surgeon at the Royal Free Hospital.

GRAHAM, W. P. G., M.B., M.R.C.S., an Inspector of Vivisection under the Cruelty to Animals Act.

HUTCHINSON, H. F., M.B., Ch.B.Vict., Junior House Surgeon at the Manchester Royal Infirmary.

Vacancies.

Free Eye Hospital, Southampton.—House Surgeon. Salary £100 per annum, with board, lodging, and laundry. Applications to Edward C. Redman, Secretary.

Newcastle-upon-Tyne City Asylum, Gosforth, Newcastle-upon-Tyne.—Junior Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board, and laundry. Applications to the Medical Superintendent.

Rochdale Infirmary.—Senior House Surgeon. Salary £110 per annum, with board, residence, and laundry. Applications to T. Elvyn Kershaw, Secretary.

Nottingham General Dispensary.—Resident Surgeon. Salary £220 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

Royal Mineral Water Hospital, Bath.—Resident Medical Officer. Salary £120 per annum, with lodging, board, and washing. Applications to the Secretary.

Births.

HIGGIN.—On November 29th, at 4 Thurlestone Road, Newton Abbott, the wife of N. F. Higgin, M.B., of a son.

O'BRIEN.—On November 26th, at 100 Prince of Wales Mansions, Battersea Park, the wife of R. A. O'Brien, M.D., of a daughter.

RANKING.—On November 25th, at Hanover House, Tunbridge Wells, the wife of Dr. Robert Ranking, of a daughter.

WHITE.—On November 30th, at 35 Elms Road, Clapham, S.W., to Dr. and Mrs. Joseph White (*née* Marie Hind)—a son.

WIGHT.—On November 26th, at 9 Regency Square, Brighton, the wife of Edward Wight, B.A., M.R.C.S., L.R.C.P., of a son.

Marriages.

COWAN—EDGELL.—On November 27th, at St. Cuthbert's Church, Thetford, Geoffrey Cowan, B.A., M.D., fourth son of the late Alexander Oswald Cowan, M.D., and Mrs. Cowan, Fyrish, Evanton, Ross-shire, to Caroline Dorothea, youngest daughter of Mr. and Mrs. James Edgell, King's House, Thetford.

HORE—WATTS.—On November 27th, at St. John's Church, Surrey Road, Bournemouth, Major Harry St. G. Standish Hore, R.A.M.C., eldest surviving son of Lieutenant-Colonel Frederick Standish Hore, Dorset Regiment, to Mary Evadne, only daughter of the late Thomas Burgoyne Watts, Esq., of Bronwylfa, St. Asaph.

JOHNSTON—TYERS.—On November 24th, at Christ Church, Hampstead, J. E. L. Johnston, M.B., B.S.Lond., D.T.M. and H.Cantab., West African Medical Staff, son of Mr. J. C. Johnston, Madras Public Works (retired), to Gertrude Mabel, daughter of Mr. J. E. Tyers, Umaria, C. India.

Deaths.

ASHBY.—On November 12th, at Hampsthwaite, Leeds, John Ashby, M.R.C.S., in his 57th year.

CAMPBELL.—On November 27th, at Torquay, William Campbell, Surgeon, formerly of Wellington Square, Hastings.

GODSON.—On November 26th, at 5m Montagu Mansions, W., Clement Godson, M.D., V.D., of Sharsted Court, Westgate-on-Sea, and late of 82 Brook Street, W., Knight of Grace of the Order of St. John of Jerusalem.

HODGSON.—On November 22nd, suddenly, at Garfield House, Workington, Isaac Clark Hodgson, M.B., C.M.Glasg., aged 55.

PINHORN.—On November 25th, at 5 Cambridge Terrace, Dover, Susan Catherine Victoire, wife of Richard Pinhorn, M.R.C.S., L.R.C.P., London J.P.

SIMSON.—On November 28th, at Muttra, India, from acute nephritis, Kate Litton, beloved wife of Major Harold Simson, R.A.M.C., and beloved eldest daughter of Ernest and Kate Litton Clarke, of Chandos Street, Cavendish Square, aged 29.

WALCH.—On November 27th, at Brighton, Charles Nash Crosby Walch, M.B., of "The Croft," Rustington, sixth son of the late James H. B. Walch, of Hobart, Tasmania, aged 44 years.

WALFORD.—On November 28th, at 120 Finchley Road, N.W., Sarah Fannie, the beloved wife of Walter G. Walford, M.D.

WELCH.—On November 23rd, at 35 Heaton Road, Newcastle, from angina pectoris, Samuel Aaron Welch, M.R.C.S., aged 55.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, DECEMBER 10, 1913. NO. 24.

NOTES AND COMMENTS.

The National Medical Union. THE medical profession of the United Kingdom is passing through stirring times. At first sight it is difficult to gauge with any degree of accuracy the precise significance of the conference of delegates of non-panel practitioners, which on November 19th last called into formal being the National Medical Union. The basis of the matter, so far as can be gathered from the published reports, appears to be twofold, opposition first to the Insurance Acts, and, secondly, to the British Medical Association. It is clear, however, that no strong society could be founded on a merely negative policy, and, as a matter of fact, several of the speakers foreshadowed an active fighting organisation to protect the business interests of medical men. The conference experienced a good deal of difficulty in deciding the qualifications of membership. It was at first proposed to exclude any medical man directly or indirectly concerned in service under the Insurance Act. If carried, this proviso would have cut out not only the unpaid non-panel members of Insurance Committees, but also the large number of non-panel men who have signed Form 43 under the Act, whereby they were entitled to attend contracted-out insured persons The meeting showed a wide difference of opinion upon the point, but a compromise was at length arrived at in a vaguely worded resolution that members should not be "on the panel" and leaving autonomy in the matter to local organisations. In other words, the National Union starts upon an apparently contradictory constitution that indirectly admits panel men to a non-panel organisation. This matter, however, may well be amended on some future occasion when things have shaped themselves into more definite form. Meanwhile, the National Medical Union is an established fact, and we heartily wish it a long and prosperous career.

Non-Panel Men and Their Pledges. FOR the Union owes its origin to non-panel men, who, in not a few instances, have faced considerable monetary loss and even ruin rather than break their pledge to the British Medical Association. The fact that a number of medical men have never flinched from that position redounds to the honour of their profession. If by a strong and resolute union they can to any extent retrieve their misfortune or secure a future revision of the medical benefits administration of the Insurance Act they will be more than justified in their common action. As already hinted, there is another field open to them, namely, the formation of a rival body to the British Medical Association. There can be little doubt that the machinery of administration and the management of the Association leave much to be desired. At any rate, there is room for another great medical organisation to undertake representative functions in directions either neglected or not adequately discharged by the B.M.A. The recent London conference was attended by no less than 95 delegates representing some fifty non-panel associations, comprising some 1,000 members. It was stated that there are altogether about ten thousand non-panel medical men in the United Kingdom, but if we deduct men of the consultant class and those holding official posts, the residue of, so to speak, active non-panel practitioners will probably not bring the total to five thousand. One point about the new Union is that its strength appears to lie mainly in the provinces, and it is significant that some of the leading spirits come from Manchester. The future progress of the National Medical Union will be watched with close interest alike by friend and foe.

Two False Medical Certificates, and the Results. DURING the past week two criminal prosecutions of medical men have resulted in two convictions. In the one case a fine of £10 was imposed, and in the other the offender was sentenced to ten months' hard labour. The discrepancy between the sentences is hardly removed by a further consideration of the facts. In one case a London practitioner took a domestic servant to a nursing home, where she died a few days later as the result of abortion. The medical man granted a medical certificate attributing death to appendicitis, peritonitis, and cardiac failure. Under these circumstances it is clear that the medical man in question ran the risk of facing the criminal courts on a most serious charge. With the consent of the Public Prosecutor, however, who approved of the summary disposal of the case in the magistrate's court, he was there convicted of wilfully making a false certificate for which serious offence he was fined £10, with £10 costs. In the other case a Manchester medical man was convicted of granting false death certificates, which were used by three persons in connection with insurance frauds. Apparently there was no suggestion that he himself had profited by the transaction, and nothing to upset his statement that he had been the innocent tool of other persons. Under these circumstances six months appears to be a drastic sentence, especially when compared with the London case. Perhaps it is to be explained by the fact that in Manchester money was concerned, while in the metropolis human life was involved. A petition might well be presented to Mr. McKenna, the Home Secretary, calling attention to the discrepancy between the two sentences, and asking that the Public Prosecutor may give as careful and sympathetic attention to the Manchester as he did to the London case, with a view to the reduction of the penalty in the latter instance.

Scarlet Fever. IT is somewhat of a reproach that scarlet fever has not been diminished in its incidence upon the United Kingdom in spite of more than a generation of advanced public health administration. There are, of course, peculiar difficulties with regard to this disease, and medical science has yet a good deal to learn with regard to its causation, its methods of propagation, and its cure. Meanwhile, it is in our midst as one of our most deadly communicable diseases. There can be little doubt that one of the great practical advances with regard to prevention has been the provision of public infectious hospitals. To be of any real use, however, accommodation of that kind should be elastic enough to meet the demands of an epidemic. In London the advent of a serious outbreak of scarlet fever has shown the incapacity of the Metropolitan Asylums Board to cope with the demands of the situation. There has not been sufficient fever hospital accommodation for the scarlatina patients, who have in consequence had to remain in their own homes. The Asylums Board has excused itself on the ground of the impossibility of finding enough nurses to staff the hospitals. There is some reason to think, however, that the fault lies in another direction—namely, the way in which the Local Government Board has during the past few years permitted its hospitals to be diverted to purposes other than those for which they were provided. At the request of local authorities fever hospitals have been used for tuberculous cases, for classified pauper patients, and so on. The Asylums Board spends money like water, and the least it could do would be to see that London is provided against the pressure of a scarlet fever epidemic. After all, the weakness of the Local Government Board is at the root of all this makeshift and muddle.

Medical Martyrs. ANOTHER name has recently been added to the already long list of medical martyrs and heroes who have cheerfully laid down their lives in the very act of trying to save those of others. The melancholy news has been received of the death, on the 3rd inst., of Dr. Hubert Liston Willcox, of Warminster, from the results of a scratch received while performing an operation on November 5th last. Septic complications supervened, and, in spite of the unremitting care and attention of his colleagues, Dr. Willcox succumbed to the effects of the poison, at the early age of 36. Few people are aware of the enormous risks run by medical men in the ordinary course of their daily work. Exposed to the risk of contracting the most deadly diseases, either by direct infection or by accidental inoculation, the medical man steps fearlessly into some fever-haunted den, or a plague-stricken camp, blind to all personal danger, if so be he can carry out his ministry of healing. Long and glorious is the roll of honour of those who have nobly fallen in the fight against disease. Truly, their fame goeth out into all lands.

LEADING ARTICLES.

THE B.M.A. SUBSCRIPTION.

ON December the 5th the representatives' meeting of the British Medical Association decided to raise the annual subscription of members from twenty-five shillings to two guineas. At the present juncture of affairs the decision must be regarded as nothing less than momentous. The profession generally has been shaken to its foundations by the changed conditions of medical practice consequent on the introduction of the National Insurance Act. In the Association itself the situation has led to the formation of two opposing bodies—namely, the panel and the non-panel parties. For the next few years, indeed, the history of the Association will probably be concerned with the disputes between these two sections. At the same time, it is not altogether easy to see how any party can thrive indefinitely upon a negative policy such as that implied in the term "non-panel." At the meeting which inaugurated the National Medical Union of non-panel practitioners, the movement was well-nigh strangled at its birth by the attempt to exclude medical men on the panel. Matters were settled only by the adoption of a half-hearted compromise, in the shape of a resolution to the effect: "That the principal condition of membership of the new Federation shall be that applicants for membership shall not be on the panel, directly or indirectly, and that all local associations shall have power of autonomy." The only possible reading of this resolution, so far as can be seen on the surface, is that the first great fighting organisation of the non-panel men is provided with a side door for the admission of panel recruits through its local branches! A more Rabelaisian situation it would be difficult to imagine. Perhaps it is in the minds of the organisers of the National Medical Union to extend its sphere of action beyond that of the mere negation of this title. Mr. William Coates, the chairman of the inauguration meeting, laid down two main principles: First, that the British Medical Association was not a proper fighting force for the non-panel members; secondly, that the British Medical Association could not serve two masters. Reading between the lines it seems not unlikely that the National Medical Union will become a serious rival of the British Medical Association. Indeed, it is in view of such a possibility that its circumstances have been here adverted to at some length. In the face of this fresh rivalry it becomes more than ever important for the Association to retain its hold upon existing members. At such a time it seems little less than an astonishing ineptitude to raise the subscriptions of members from twenty-five shillings to two guineas. The result will certainly be to lead to a large number of resignations of membership, which would cripple the Association for many years to come. A more crucial point for the representatives to consider, in our opinion, is its present financial position. One of the representatives on the 5th of December, Dr. Montgomery Smith, handled that point with his accustomed force and clearness. His words amounted to a strong indictment of the financial state and administration of the Association. As recently stated in these columns, it is of little use resorting to various spendthrift resources—such as increasing subscriptions, raising advertisement rates, and increasing powers of borrowing, and the like. The straightforward course is to hold a searching expert investigation into the affairs of the Association, and, above all into the cost of the staff and the production of the *Journal*. The affairs of the Association have for many years been in the hands of a few persons whose management has led to the present crisis. The recent alterations in the constitution of the Association were intended to increase the control of members, but that hope has not been realised. Every change has been carefully engineered in the direction of government by Council. The want of confidence of members in the Council on the occasion of Mr. Smith Whitaker's acceptance of an insurance post was followed by adverse resolutions from nearly every branch in the United Kingdom. The Council, however, with a few honourable exceptions, sat tight in their places, and most of them are there to the present moment, although the policy of the Association has in the meantime made a *volte-face* from non-panel to panel. If the British Medical Association is to be saved, its *Journal*—a magnificent property—must be put under strict business management: its finances must be reduced to system; its control must be representative in reality as well as in name; it must be relieved of the curse of central control; its annual open meeting of members must be restored; its exercise of disciplinary powers carefully checked and guarded; and the burden of lay parasitism with which it is now permeated reduced to manageable proportions. Instead of increasing subscriptions, why not cut down expenses? The loss of the British Medical Association to the profession would, in our opinion, be irreparable. It looks, however, as if an early consummation of the kind were not beyond the range of practical politics unless its future course is inspired by wiser and saner collective action than that which has ended in the present crisis.

CURRENT TOPICS.

The Ptosic Hamlet.

Shakespeare's appeal is well nigh universal. The truism applies not only in its plain straightforward sense to those who read the plays and delight therein, but also to the mass of controversialists whose true delight is to convert molehills into mountains, which, pseudocyesically inflated with windy nothings, eventually produce a very mouse of literary accomplishment. We have the erudite enthusiasts who say that the plays were not written by Shakespeare but by another man who used his name; those who say that Hamlet was mad and those who say that he was only unconsciously assuming madness. Now let us look to Hamlet's physical condition. Hamlet is conventionally played as a lean, dark, saturnine man. Whence this convention arose it is hard to say, for the typical Dane is surely fair, and the only remarks of auto-diagnostic significance that Hamlet makes show him the very opposite of his usual conception. "Too, too solid flesh" encumbers him. He is "fat and scant of breath." He sways indecisively between profoundest gloom and hysteric gaiety. Read the play and consider how such a man would be treated to-day. The diagnosis is clear at last. A gouty diathesis and auto-intoxication with protein fermentation fills the bill and Hamlet's abdomen. We would promptly do a gastro-pexy and prescribe liquid paraffin. Of course, the real difficulty lies in the fact that Hamlet fits each new pathological theory of his condition as well as, if not better than, the last. Most of the thousand and one ills that flesh is heir to have been aptly fostered on the unhappy prince at one time or another. Still he survives and will probably go on as a diagnostic dummy, at any rate, till the question of his authorship is finally decided.

The Newcastle (Ireland) Hospital Again.

In last week's issue, speaking of the Royal National Hospital for Consumption at Newcastle, Co. Wicklow, we stated that, as far as was known, the Board had not receded from the position that the discussion of questions of treatment was one of its functions. On the day our paragraph appeared the Board made it clear that it still held this extraordinary view of its responsibilities. In the annual report, presented last Wednesday, the Board states its belief that the course taken, *i.e.*, the introduction of a particular method of treatment in opposition to the views of the consulting and visiting medical staff, was called for "both in the interests of the patients and of the public." The Chairman, in moving the adoption of the report, put matters more plainly: "Time has justified the course which we took in the beginning of the year. The results of treatment for the first nine months of the year showed marked improvement." The degree of judgment exhibited in such a statement as this is sufficient evidence of the ability of the Board to express an opinion on such a matter. Even the most optimistic of skilled observers would admit the necessity of a much longer period before pronouncing any opinion.

Ambulance Service for London.

The existing arrangements in London for the speedy removal of street accident cases to hospital and the rendering of efficient first aid have long been a subject for adverse comment. It is gratifying to learn, therefore, that a scheme for the establishment of a complete ambulance service was adopted by the Metropolitan Asylums Board last week. This scheme provides for the control of the organisation from the Ambulance Department of the head office of the Board, just as the present infectious ambulance service is now controlled, the two services being kept, of course, perfectly distinct. The seven existing stations in the metropolis will be supplemented by ten or twelve small additional depots exclusively for accident ambulances. Provided these are judiciously placed, almost every part of the metropolis will be within a mile or thereabouts of an ambulance station. Each of the new stations will, like the existing ambulance stations, be connected by direct private telephone line with the head office. It will be essential to maintain a continuous day and night service. Thus it is recommended that one accident ambulance should be provided for each station, with a small additional number in reserve for breakdowns, accidents, repairs, etc. With the aid of the proposed rapid ambulances, supplemented in certain circumstances by the wheeled and hand litters possessed by the police (about 400 in number), the St. John Ambulance Association, and the Bischoffsheim Association, it is believed that it will be impossible for any accident case in any part of London to remain for more than the few minutes necessary to make the call without first aid and the means of conveyance to the nearest hospital. It is also proposed to rely on existing telephone facilities and public call offices (which already number 2,770, of which number 15, and many railway-station call offices, are open day and night), supplemented, as may be found necessary, by additional means of calling—either street pillars or additional call-boxes. Only a few seconds would be occupied from the time of the call to the dispatch of the ambulance, and by arrangement with the police the passage of ambulances through the streets will be facilitated as is that of fire engines. Generally, no doubt, the call for the ambulance would come from the police, who will be thoroughly well informed from the outset of the arrangements; but no doubt it will not be long before the general public becomes acquainted with the system. The minimum necessary staff for each ambulance station will be two men in constant attendance, both capable motor drivers, with an intimate acquaintance with the streets in the area within which they would be operating, and both trained in first aid. This means, allowing for a weekly rest day, providing seven men per station, together with a few additional men for relief duty in cases of sickness, annual leave, etc. The capital expenditure is estimated at £18,680, to which must be added the cost of any sites purchased for new ambulance stations, and the annual expenditure at £17,860. The provision of the service is proposed under contract with the London County Council, the cost of that part of the scheme which is clearly separable from the Board's existing service to be defrayed out of the county rate. Thus equipped, the metropolis should, ere long, be second to none in respect of its ambulance service.

Railway Sanitation.

CLEANLINESS is comparative. Railway trains are now cleaner, no doubt, than they were twenty years ago, but they are still far from being perfect. The companies are providing more sanitary accommodation of some sort or another, but their standard is still far below what should be tolerated. Lavatories at stations are on the whole fair, and the more odoriferous examples are not so much the fault of the system in vogue as of its application. The glaring faults lie in the methods of disposing of sewage on trains. To scatter human excreta broadcast along a track should be unthinkable in an age such as ours. Railways run through thickly populated country, and expresses dash through our largest towns leaving behind them matter at the best offensive and at the worst dangerous to life. Water supplies to cities are carefully chosen. Mountain streams are tapped and their pure water carried for miles so that the city may be safe. At any moment these streams may be contaminated by a defæcating passenger, and this danger is the greater because it is wholly unsuspected. Some American companies make arrangements for the sewage to be removed from cars when they are on sidings for the night. There is no reason why some such system should not be universal. The present one, at any rate, is an intolerable anachronism. It is not many years since a serious outbreak of typhoid fever among railway navvies on an American line was proved to be due to contamination of the line from passing trains.

Wisbech and the Death of Dr Dimock.

THE tragic death of Dr. Dimock at Wisbech on the eve of a legal trial for slander is still fresh in the public mind. It was followed by local riots in which extreme resentment was shown against certain local medical practitioners under the belief that they had persecuted deceased. As a matter of fact, the local medical opposition against the Insurance Act was of a determined character, and the importation of Dr. Dimock as a panel doctor was followed by a general boycott. In the course of time deceased made certain accusations against Dr. Meacock, who had instituted criminal legal proceedings in his own defence. It is now found by the coroner's jury that Dr. Dimock committed suicide when "temporarily insane," and expert evidence showed the presence in the body of 2.67 grains of morphine and of 6.7 grains of veronal. If, as the coroner appeared to hint, the act of suicide was more or less tantamount to tacit admission of guilt on the part of deceased, the character of Dr. Meacock is to that extent vindicated. Under the circumstances, the actual truth can hardly be more directly disclosed—and most sensible persons will agree with the advice of the coroner that it would be best that all parties, including those who thought, and perhaps wrongly thought, there had been some injustice in the case, should bury the trouble in the grave of Dr. Dimock. It is much to be regretted that the local Insurance Committee have not adopted a like conciliatory policy in its appointment of a successor to deceased on the Wisbech panel.

Cocaine Snuff.

A FIRM of chemists in Birmingham has lately been fined for selling a poison in a bottle which was not properly labelled. The case revealed some curious circumstances. An inspector of the Pharmaceutical Society was supplied on request with 102 grains of snuff which on analysis was found to contain 2.34 grains of cocaine. The bottle was labelled with the defendants' name and also with the words, "The Snuff. G. Standfast, Esq. Book A, No. 1." We may say that the inspector's name was not G. Standfast. The defendants said that they treated the snuff as a prescription. Mr. Standfast obtained the prescription from an eminent physician and allowed his friends to ask for the snuff. The prosecution alleged that the snuff could be bought at nearly every licensed victualler's and tobacconist's, and offered to call evidence to show that the cocaine snuff habit had taken such a hold on a certain section of the population that men had been dismissed from their employment owing to the habit. The important facts of the case were not controverted, and the Stipendiary imposed a fine of 20s. and costs, but agreed to state a case on the points of law submitted by the defendants. Our idea, and, we believe, the public's idea, of a prescription is that it is a matter between patient and physician. But we should not be greatly surprised if the law held otherwise. We know the law.

The Hospital Journals.

EVERY association of men and women working together for some common cause, or united by ties of fellowship, requires its magazine, no matter whether it be a weekly journal or an annual report, to serve as a visible bond of union between past and present members. Medical students are no exception to the general rule, and the modern hospital gazette, it will be admitted, caters remarkably well for the class for whom it is intended. Many an aspirant to medico-literary fame has first tried his hand in the columns of his hospital journal, which, indeed, has sometimes to beg for contributions. The contents of an average number, vigorously censured by an ever-watchful editorial committee of the hospital staff, usually consist of a clinical lecture, a cartoon, a few smart editorial paragraphs, local news, and, last but not least, plenty of sporting notes. Now and then serious articles appear which might be considered worthy of a more serious publication and of a wider circle of readers, but it may be remembered that many of these appeal to that large number of old hospital men—long since qualified, and some of them retired—who still take a deep interest in the doings of their Alma Mater. We understand from the *Guy's Hospital Gazette* that a scheme is in progress whereby a certain degree of co-operation of the various hospital journals in London may be obtained in order to discuss in their respective columns matters of current and vital interest to medical students. Among the subjects with which it is proposed to deal in this concerted manner are the proposed changes in the University of London and the question of anatomical terminology. We might suggest, in addition to these, such topics as the art of prescribing, the methods of dealing with different types of patients with a view to private practice, the recognition of minor ailments, the elementary principles of hospital administration—especially for senior students and duly-qualified men. No doubt other subjects will suggest themselves for discussion collectively in all the hospital journals, so that the current opinion of medical students, and practitioners also, can be more effectively dealt with than at present is the case.

The Deficiency Diseases.

Much interest has arisen of late years in regard to a group of disorders which are believed to arise not from any extraneous cause, but from some inherent deficiency in the diet which makes itself felt in the tissues of the body. The question was dealt with at a recent meeting of the Therapeutical and Pharmacological Section of the Royal Society of Medicine in a discussion opened by Professor F. G. Hopkins, F.R.S., who showed, as a result of his own experiments, that the removal of substances, minute in amount and of unknown nature, is able to produce a very marked effect upon the physiological properties of a dietary. He has proved that young rats absolutely cease to grow if fed upon a diet consisting of purified materials, such as after thorough extraction with alcohol. The results of the deficiency of iron, lime, fat, or vegetable acids in a diet are familiar to all, and the so-called zeistic theory of the production of pellagra is based upon the deficiency in maize of the aromatic amino-acid tryptophane. These scientific "vitamines," the absence of which is believed to be the cause of scurvy, beri-beri, and, perhaps, of pellagra also, may, as Professor Casimer Funk has pointed out, be naturally lacking in certain foods, or else they may be artificially removed by the process of milling, high temperatures, or extraction during cooking, when the decoction is rejected. The results of feeding human beings on polished and unpolished rice with regard to the incidence of beri-beri seem to indicate pretty clearly that there is more than a casual connection between the hypothetical vitamine in rice and the development of the disease. Other observers have drawn attention to the relationship of the consumption of other cereals to deficiency diseases. No doubt the science of biochemistry will have something more to say upon the matter in the near future.

PERSONAL.

Dr. P. W. Saunders, M.B., M.R.C.P.Lond., has been appointed Assistant Physician to the Royal Free Hospital.

Dr. Stanley Wyard, M.D., B.S.Lond., M.R.C.P. Lond., has been appointed Pathologist to the Bolingbroke Hospital, S.W.

Dr. C. F. Hadfield has been elected Chairman of the recently-formed City and North-East London Non-panel Practitioners' Association.

Mr. Harold Clifford, M.B.Lond., F.R.C.S.Edin., M.R.C.S.Eng., L.R.C.P.Lond., has been appointed Honorary Gynæcologist to the Salford Royal Hospital.

Dr. Edward Austin Fox, M.D., of New Brighton, formerly of Warrington, Consulting Surgeon and a Life Governor of the Warrington Infirmary, left net personalty £28,908.

Professor John Campbell, M.D., of Hazelwood House, Dundrum, Co. Dublin, who died on September 11th, aged 78, left personal estate in the United Kingdom valued at £21,314, of which £5,036 is in England.

Surg.-General Sir Launcelot Gubbins will read a paper on "Jean Dominique, First Baron Larrey; His Life and Work," before the United Services Medical Society, at the Royal Army Medical College, Grosvenor Road, S.W., on Thursday, December 11th, at 5 p.m.

A plaster cast of the late John Hunter from the mask in the Royal College of Surgeons of England, presented to the trustees of the National Portrait Gallery last October by Messrs. D. Brucciani and Co., has now been placed on exhibition in the Sculpture Gallery.

Dr. Preston King, Mayor of Bath, was presented last week by East Anglians resident in Bath with a silver rose-bowl. It was pointed out that one of Dr. Preston King's ancestors had been chairman of Norwich Council, and that his portrait in his robes of office was painted by Opie.

Mr. James Rutherford Morison, M.A., M.D., F.R.C.S., has been appointed Consulting Surgeon to the Royal Victoria Infirmary, Newcastle-upon-Tyne, in recognition of his distinguished services to the Institution, and an illuminated address was presented to him on behalf of the Governors at their last quarterly Court.

Dr. D. G. Thomson, Honorary Secretary of the Mid-Norfolk Division of the East Anglian Branch of the British Medical Association, and Honorary Secretary of the Local Medical Committee for Norfolk, was the recipient the other day of a handsome presentation of plate from the medical practitioners of Norfolk in recognition of his services rendered to them.

FRENCH CLINICAL LECTURE

ON

MENINGEAL HÆMORRHAGE IN CHILDHOOD.

By PROFESSOR HUTINEL, M.D.,

Physician to the Hopital des Enfants Malades, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

DURING a period of three weeks, by virtue of those curious "runs" which occur in medical practice, we have had in our wards three examples of a rather rare affection, and I cannot do better than make it the subject of my lecture.

The first case is that of a little girl, æt. 3½, who weighed 7½ lbs. at birth, and was brought up by a nurse in the country. The child's mother had had five pregnancies, all of which went on to term, and she had lost two children, one of meningitis at the age of 15 months. This particular child had had convulsions, and at 12 months of age she contracted measles since which she has been subject to bronchitis. For the last three weeks this little girl has lost her appetite and has been suffering from constipation; then, too she has had two or three well-marked epileptiform convulsions. Her condition on admission to hospital was as follows:—

She was very emaciated and drowsy and lay on her back. There was no temperature. She presented numerous peri-orbital and auricular ecchymoses. Others were seen on the trunk, on the outer aspect of the left thigh, and on both lower limbs. The belly was retracted, and she displayed the *tache cerebrale*, or vaso-motor white line. The patellar reflex was more marked on the left than on the right. Babinski's sign was noted on one side, and, on the other, flexion of the toes. Respiration was irregular, there was stiffness of the neck, but no inequality of the pupils nor strabismus. Lumbar puncture gave issue to a blood-stained fluid under pressure.

There was slight improvement four days after this examination, that is to say, on December 6th. On the 16th, she had an attack of vomiting, and the little patient fell into a state of torpor, as if she were going to have a relapse. The ecchymoses, which had been clearing up, came out afresh. We again performed lumbar puncture, prescribed aperients and a vegetarian diet, whereupon improvement once more set in, and has since continued in such wise that she may now be regarded as on the road to recovery.

The second case also concerned a little girl, æt. 2, born before term (eight months), after a laborious confinement, and she is reported to have weighed only 3½ lbs. at birth. No history of syphilis in either father or mother, who were both in excellent health. They brought her to the hospital on account of stiffness of the legs of three days' standing.

On waking up on the morning of November 24th she complained of feeling sick. In the course of the day we noticed that she dragged the right leg. On November 25th, both legs were affected. The reflexes were exaggerated, there was well-marked stiffness of the neck, and a positive "fan sign." She had also slight facial paralysis on the right side, inequality of the pupils and a rapid pulse. Lumbar puncture gave issue to a clear fluid, *not* under pressure. It contained albumen, red corpuscles and lymphocytes. We tried the intra-dermo-tuberculin test which yielded a positive result.

We were struck in this case by the very pronounced hyperæsthesia, so marked as to cause her to cry out on the lightest touch. This sign, it is true, does not militate in favour of tuberculous meningitis, but rather of poliomyelitis; nevertheless, as there was no change in electric contractility, the latter diagnosis does not commend itself.

In this case, again, we are in presence of meningeal hæmorrhage. The stiffness of the neck and the paralysis of the limbs persist, and the cerebrospinal fluid still contains red blood corpuscles. Wassermann test negative. It may be that the hæmorrhage is due to tuberculosis, but it can safely be asserted that it is not attributable to tuberculous meningitis.

In the third case, the patient was a child, æt. 12, previously very intelligent, who had suffered from time to time from headache. When out walking one day he suddenly felt unwell, got into an omnibus to return home, and became comatose. In carrying him to his bedroom it was remarked that the limbs were stiff. A doctor who was called in advised removal to hospital.

On examination we noticed slight deviation of the head and eyes, with unequal pupils and paralysis, especially pronounced on the right. We diagnosed meningeal hæmorrhage, which was confirmed by the results of lumbar puncture. After four or five days the little fellow gradually recovered from his state of torpor and got up, but he dragged his leg and had well-marked incoordination of movement and nystagmus. He left hospital a few weeks later and came back for examination every six months. To begin with, his gait was irregular and rather "inebrious," and the reflexes on the right side were exaggerated. On December 12th, 1912, his attitude was normal; in fact, the child may be considered to have recovered.

The more we study this somewhat uncommon affection, the more numerous do cases of the kind seem to be and the researches of which it has been the object during the last few years enable us at present to recognise its existence with greater ease. What we must bear in mind is that meningeal hæmorrhage in infancy is far from rare. There may be hæmorrhage into the pia mater, either on the convexity of the encephalon or behind, cerebellar, extending right into the spinal canal. These hæmorrhages are often met with in lying-in hospitals, and are attributed to traumatism, to the compression of the neck by a twisted cord, or some interference with the venous circulation. I can recall the case of an infant, born in a state of asphyxia, who had convulsions. Under bromide these disappeared, but we are nevertheless justified in apprehending latent encephalitis.

There sometimes seems to be a sort of predisposition, but as a general rule the victims are prematurely born infants or debile twins. An infant, æt. 1 month, after a chill, had convulsions, lumbar puncture was performed, and the existence of meningeal hæmorrhage confirmed. The infant recovered, but a year later the child was notably behindhand.

We are apt to get symptoms of coma in these newly-born infants with petechiæ, subicterus and black urine. These are cases of septicæmia (coli bacillus or streptococci) which end fatally. We may get thrombus of the sinuses or other veins and "red softening" in somewhat older children.

Meningeal hæmorrhage may occur after a fall or shock of some kind, but the form which presents most interest to practitioners is that met with in connection with hæmorrhagic states such as purpura. In these cases we must make a very guarded prognosis, because they may end fatally, as in the case mentioned above. We also meet with meningeal hæmorrhage in connection with the grave infectious diseases, small-pox, measles, typhoid, septicæmic states, malignant scarlet fever, grave icterus and leucæmia.

It may be due to simple disturbance of the circulation. I remember a little boy, æt. 4, who, in the course of an attack of whooping cough, fell into a state of coma after an attack of suffocation. There was stiffness of the neck and contraction of the limbs. Death proved to be due to meningeal hæmorrhage. The same thing has happened in the course of epileptic attacks.

Meningeal hæmorrhage is most frequently caused by irritation of the meninges due to bacillary meningitis or to syphilitic pachymeningitis. We sometimes meet with it in the course of an attack of cerebro-spinal meningitis. Marfan and others have called attention to the occurrence of fibrinous hæmorrhagic meningitis in connection with septicæmia, accompanied by meningeal hæmorrhage *en nappe*.

To sum up, meningeal hæmorrhage is met with in newly-born infants, in infants who have become infected, and in connection with hæmorrhagic states. It may also follow strain or effort in presence of meningeal irritation, and is almost always of venous origin in infants.

In most cases the symptomatology is reduced to somnolence and a tendency to coma. Conjugate deviation of the eyes and head is less frequent than in cerebral hæmorrhage. Epileptiform convulsions are common, and are usually of the Jacksonian type. Contracture is usually present, and Kernig's sign is pretty constant. In older children we may meet with hemiplegia or monoplegia. Sometimes there is amaurosis or incontinence of urine. The reflexes are exaggerated, but should there be hypertension of the cerebro-spinal fluid they may be abolished. Vomiting is common, and respiration is often dissociated, as in tuberculous meningitis. The temperature may rise and reach 104° F., or more when death is imminent.

Then, too, there are varied latent unrecognisable forms Two types have been described in the newly-born—the blue and the white. The latter form is the most serious, and the victim succumbs with extensive effusions of blood. Lumbar puncture gives issue to a more or less manifestly blood-stained fluid.

With regard to prognosis, this is not quite as grave as it used to be, and recovery is not uncommon, though the forecast must be guarded in respect of the child's future. Epilepsy is very apt to supervene later on in life.

When we have arrived at the diagnosis of meningeal hæmorrhage, we must see that the patient is kept very quiet, with ice to the head; the limbs are wrapped in wadding, the bowels are cleared with enemata and aperients, and recourse should be had to lumbar puncture except in hæmorrhagic subjects. Bromide is usually of benefit in these cases by diminishing cerebral congestion.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Dr. Henri Claude, Professeur Agrege in the Faculte de Medecine of Paris. Subject: "Defensive Reflexes: Their Semeiological and Prognostic Value."*

ORIGINAL PAPERS.

ISOLATION AND QUARANTINE IN THE MORE COMMON INFECTIOUS DISEASES. (a)

By CLAUDE B. KER, M.D.EDIN., F.R.C.P.,
Medical Superintendent City Hospital, Edinburgh, Lecturer on Infectious Diseases, University of Edinburgh.

THE author remarked that the regulations for the isolation and quarantine of infectious diseases were to some extent traditional. Views on the subject were changing, and a reconsideration of the rules seemed necessary. Public authorities and schools were tied by the opinions generally held, and before they could change their regulations they must have the assurance that professional opinion supported them. In some cases much time and money would be saved by relaxing the rules; in others, the question was more an academic one, as the patients' disability lasted longer than their infectivity.

In scarlet fever, the practice in Germany, America, France, and Britain was to isolate for six weeks. This was probably based on the fact that in the average case desquamation was complete in that time. But was there any reason to believe that desquamation was ever infectious? Scarlatina was infectious before desquamation began, and might be infectious after it had ceased. The desquamated scales might share whatever danger was to be attributed to fomites. If the skin were disinfected it was probably as harmless as the patient's clothing after disinfection. Drs. Lauder and Millard had cut down their minimum detention periods to four weeks, disregarding desquamation, and there had been no increase of cases of infection. Their average detention period for hospital patients was 36 days. The average period in Edinburgh was 45 days. This meant a large outlay in money to the ratepayer. Scarlet fever was to be regarded as a moderately infectious disease for two weeks after its onset. Infection usually ceased in the second fortnight; after the second fortnight very few cases remained infectious. Could the detention period not be reduced? What would the attitude of the doctor be if a return case followed the sending out of a patient still desquamating?

There might be healthy carriers of scarlet fever just as there were in diphtheria.

These could not easily be checked. If a scarlet case had a nasal discharge or other possible source of infection, he would advocate detention even for 20 weeks; but if in the average case a five weeks' minimum detention was sufficient, why should the ratepayer be made to pay for six? Long detention in hospital did not diminish infectivity.

(a) Paper read before the Edinburgh Medico-Chirurgical Society, December 3rd, 1913. See page 646.

For the quarantine period in scarlet fever he accepted Goodall's statement—namely, six days. He had never known an incubation period longer. Why not cut down the ten days for schools to seven?

In diphtheria the causal organism was known. He would advocate keeping patients till on two successive occasions no bacilli were found. A quarantine period was useless. As soon as contacts gave negative results they might be regarded as non-infectious. To keep contact children away from school for ten days and send them back without throat examination was useless.

In measles infection did not outlast the catarrh. Measles cases with a rash could hardly be turned out of hospital, but in private houses a great relaxation of present practice might easily be allowed.

Dr. Ker said he was not to be taken as opposing the hospital treatment of measles. He was strongly in favour of it, but not on the ground of infection. He thought more lives were saved in Edinburgh by the hospital treatment of cases of measles and whooping-cough than by any other means. His quarantine period for measles was fifteen days. Once in seventeen years he had seen an incubation period of seventeen days, but he kept to the fifteen-day period. He acted in accordance with the rule rather than with the exception.

Nine or ten days elapsed from the moment of infection to the first sign of the disease, or thirteen days till the appearance of the rash. Might it not be possible to allow contacts to attend school during at least part of the incubation period? In some schools attendance was allowed for eight days. The contact was kept away from the ninth to the fourteenth day, and only five days were lost. The practical difficulty arose in ascertaining whether infection might have occurred at a first or subsequent exposure—a difficulty which was the greater since early symptoms might be overlooked.

In rubella the infection existed before the rash and ceased after it, and it was doubtful if there were any infection during the period of the rash. An ample detention period would be ten days. The incubation period was from the twelfth to the twentieth day. He had never known it less than thirteen. The quarantine period was thus twenty-one days.

In whooping-cough the patient ceased to be infective when the whoop developed. If a case developed whooping-cough in a ward, every susceptible child took it. It was infective in the catarrhal stage. But when a child had been admitted after that stage no other case developed. This view received confirmation if one accepted the bacillus of Bordet and Gengou as the cause of whooping-cough. The bacillus could readily be found during the catarrhal stage, but not afterwards. Rigid isolation in a private house was not necessary after a week or ten days.

Chicken-pox was infective till the crusts separated. Incubation was always over twelve days. Contacts might go to school for ten days after exposure. His quarantine period was twenty-one days.

The usual detention period in mumps was put at three weeks. This might be too short, but was usually far too long.

He would put the detention period at one week from the subsidence of the swelling. Alternatively he might suggest a fortnight from the beginning. This would cover the cases of orchitis and pancreatitis. He had never known these occur after the ninth day. He would exclude contacts from school from the thirteenth to the twenty-sixth day.

He would like to put the following questions forward for discussion:—

1. Might not the minimum detention period for scarlatina be cut down from six weeks to five?
2. Was there any proof that measles was infectious after the catarrhal stage, or that whooping-cough was infectious after the whoop had begun?
3. Might not the early part of the incubation period in rubella, chicken-pox, measles, and mumps be utilised for educational purposes?

NOTE.—A brief report of the discussion will be found on page 646.

THE TREATMENT OF SCOLIOSIS. (a)

By PAUL B. ROTH, M.B., CH.B.ABERD., F.R.C.S.ENG.,

Surgeon, Kensington and Fulham General Hospital; Senior Orthopædic Clinical Assistant, London Hospital.

I PROPOSE to confine my remarks to the examination and treatment of a patient with scoliosis.

The Spine.—The patient is stripped to expose the whole of the iliac crests: the clothes are prevented from slipping down further by a large safety-pin. The hair is coiled up out of the way.

(*a*) From Behind.—After a general view, noting the "habitual position," the patient, standing with feet together and knees straight, completely flexes the spine, the head and arms hanging down limply. If the surgeon then observes the "horizon" of the back from different levels and from in front as well as from behind, he will at once notice any structural deformity: the ribs, or the erector spinæ in the lumbar region, will project more on one side than on the other. If there is no projection on one side more than on the other the case is one of "postural scoliosis"; if there is projection the case is one of "structural scoliosis," and the amount of rotation is at once recorded by using a malleable tin tape (1). This is moulded transversely across the ribs posteriorly from the lower angle of one scapula to the lower angle of the other, and also across the loins midway between the twelfth rib and the iliac crests, with the spine still fully flexed. A tracing of the moulded tape at each level is made on paper; this is cut out with scissors, pasted into the case-book, and a permanent record of the rotation thus obtained. If the patient is seen years later, one can at once discover by taking a similar moulding whether the deformity has diminished or increased.

It is difficult to understand why this extremely simple method has not been generally utilised. Latterly Dr. Abbott, of Portland, Maine, has been using a photograph of the "horizon" of the back as a record of the amount of deformity, but a careful inspection of his paper (2) shows us how misleading these photographs may be. It is so difficult to get the patients flexed to the same degree both in the photograph taken before treatment and in that taken after, and if they are not flexed to the same degree the photographs are valueless. Anyone accustomed to examining cases of scoliosis by observing the "horizon" of the back at different levels knows what an enormous change can be produced by the patient flexing her spine a little more, or extending it a little more. If the deformity is low down, it can be entirely made to disappear from the "horizon" by the patient not flexing her spine so much: if she be then asked to slowly fully flex her spine again, the deformity gradually comes into view. In many of Dr. Abbott's photographs, which are intended to show that he has got rid of a hump, the position in which the second photograph has been taken is quite enough to hide it, without any treatment whatsoever. This chance of error is entirely absent in working with the tin tape, for the tracings to be compared are always made at the same level. The deformity should not be recorded

---

(*a*) Read before the Section of Orthopædics, International Congress of Medicine, London, August, 1913.

by observing how far the spinous processes have deviated from the middle line, as is sometimes attempted by drawings or photographs, for, besides being exceedingly difficult to measure accurately, the amount of deviation is not a measure of the amount of scoliosis. Often a severe amount of deformity is present, and yet the spinous processes are still practically in a straight line. The following passage from Mr. Tubby's "Deformities" (3) will serve to emphasise this point:—"In fact, we must judge of the presence or absence of curvature, not from the lines of the spines at all, but by rotation signs—*e.g.*, rib prominence backward on one side. And we may go further still, and add that if the rotation signs indicate, say, curvature to the right, whilst the lines of the spines suggest curvature to the left, we must accept the evidence of rotation, and disregard the line of the spines."

(*b*) From the Side.—Observe the state of the antero-posterior curves. In scoliosis the normal antero-posterior curves are exaggerated or, less commonly, diminished.

The commoner condition is an exaggeration of the dorsal curve: the patient stoops and pokes the head forward. To bring back the centre of gravity to the middle of the body, compensatory exaggerated lordosis develops in the lumbar region; this makes the abdomen prominent. The less common condition is where the normal curves appear to be flattened out. Accompanying both these types is a drooping downwards and forwards of the scapulæ.

(*c*) From the Front.—Observe the degree of development of the chest, and look for a prominence of the ribs on one side or the other. Often the chest is what one calls badly developed, being flat or even hollowed.

The Legs.—Difference in the length of the legs is best examined for by placing the thumbs on the anterior superior spinous processes, with the patient standing. If both thumbs appear to the eye to be on the same level, the legs are of equal length. If they appear to be at different levels, the legs must be measured with the patient lying down in the ordinary manner. Slight differences in the length of the legs are of little if any importance.

Prognosis.—Having observed the "habitual position" in which the patient stands, it is now necessary to ascertain the "best possible position" in which she can be placed by the surgeon. This is not found by hanging her from a trapeze, but by making her stand as erect as possible, with head straight, shoulders level and drawn back, chest out, abdomen in, and arms stretched down. (If one leg be short a suitable block should be placed beneath the foot.) She may only be able to maintain this position unaided for a few seconds, but if she can maintain it at all, then the parents may be assured that the patient can be trained to assume this position naturally, so that the "best possible position" will become the "habitual" one.

When a case with even severe structural deformity is put in the "best possible position" often much of the deformity is masked, and this is what the surgeon desires. For, once there is structural deformity of the ribs, it cannot be got rid of. This must be carefully explained to the patient's parents. If photographs are taken of the patient, they should be taken on the first day of examination, and one set should be taken when the patient is in the "habitual position," and another set when the patient is in the "best possible position." In the past a common practice has been to take the first set all right, but omit taking the second set until after a course of treatment. The great improvement demonstrable in this second set is then attributed to the treatment, whereas just as favourable a set of photographs could have been obtained before ever the treatment was begun. We are even not quite free of this method yet: I feel sure Dr. Abbott will not mind my again referring to his paper (2) (Case 6). In the first photograph (Fig. 1) the patient, afflicted with severe infantile paralysis of one limb, is shown in his "habitual position"; in the second photograph (Fig 3) he is shown after treatment, much improved, *but with a block beneath the short leg.* In order to judge of the effect of treatment, the block should have been placed beneath the short leg when the first photograph was taken.

The Clothes.—After examining the patient, she is told to dress, and is placed in the "best possible position" as each garment is put on, while the surgeon observes if it is sufficiently loose. In 90 per cent. of cases the clothes across the chest are two or more inches too tight; and very little improvement can be obtained in such cases if the clothes are not attended to first of all.

As regards corsets, the patient should continue to wear those she is accustomed to, provided they can be made loose enough. (*a*) If the corsets are held in position by straps over the shoulders, as in young girls, the stockings should be kept up by garters, and not by suspenders attached to the corset, for the continual pull of these is quite enough to make a delicate child stoop. Boys should wear a belt, or Y-shaped braces which meet together behind high up, and so leave the scapulæ free.

TREATMENT.

This will depend on the views of the surgeon. The different methods at his disposal are (1) so-called "gradual correction" in a support or corset; (2) so-called "rapid correction" in a plaster jacket; (3) gymnastics; (4) combinations of (1) and (2) with each other or with (3).

In spite of bold assertions such as that scoliosis "yields to treatment far more readily than either bow-legs or club-feet," or that "the parts entering into the deformity are actually turned back into their normal positions," I am more than ever sure that the structural deformity of scoliosis—*e.g.*, a rib prominence, once present, can never be got rid of. Holding this opinion, the only method which seems to me the rational one is the gymnastic, and that particular form of it which is known as the method "by Posture and Exercise" (4) is the one which in private I solely practice. I believe that violent methods, and methods which have caused the death of patients must be considered violent, will temporarily cause a rib prominence to disappear, will even temporarily produce a rib prominence, but I do not believe that these changes are permanent or that the vertebræ themselves even become changed at all. The treatment I adopt, which was introduced by my grandfather, Dr. M. Roth, and elaborated by my father, Mr. Bernard Roth, is conducted on the following principles:—

Attention to Dress.—If the clothes are not loose enough to allow of patients assuming the "best possible position" the efforts of the surgeon are largely wasted. It often happens that patients are exercised undressed—a quite unnecessary proceeding—and are then allowed to dress again in their badly-fitting clothes, which at once cause them to assume the "habitual position," the very position which the surgeon wishes to avoid. It is for this reason that no improvement in carriage is observed in patients after wearing spinal jackets, for they are fitted with the patient hanging from a trapeze or lying twisted on a sling, neither of which methods make the patient assume the "best possible position" at all, and any effort on the part of the patient to assume a better position is prevented by the jacket. Often when such a patient is placed in the "best possible position" the sides of the jacket or support she has been wearing will not meet in front for several inches. Yet this is the appliance which it is confidently hoped will straighten up the patient.

Daily Systematic Training, for from one to three months, of the spinal and other muscles, including the development of the thorax.—As I hope to give some of you a demonstration of the necessary exercises, I will only allude shortly to them here.

For a month the patient is made to do symmetrical exercises, in the "best possible position," regardless of the particular variety of curve present. After a month she is examined undressed again, and a position of the arms decided upon which makes the spine look straightest. This position may be arms up holding a stick; elbows grasped above head; right arm up left out; left arm up right out; right arm up left grasping right wrist; or left arm up right grasping left wrist.

(*a*) A good make of corset is that known as "Spirella."

Thereafter many of the exercises are done in that position. They are all done with the clothes on. At first they are easy, but gradually they are made more and more difficult, as the strength of the patient increases. They consist largely of concentric and eccentric movements, patient resisting or surgeon resisting, and of simpler ones carried out under the supervision of assistants. In each case the surgeon has to feel his way and gradually increase their severity. The exercises are done daily; only thus can the effect of habit be overcome and the weak muscles quickly made strong. The patients are not treated separately, but several together in the exercise-room at the same time. While one is doing an exercise with the surgeon another does one with an assistant, while a third and fourth are resting on suitable couches, waiting their turn. Working on this plan with two assistants one can efficiently treat twenty patients in an hour and a quarter. An advantage in treating patients together, apart from the saving of time, is that each profits from another's example, the intelligent ones unconsciously assisting the backward.

Daily Re-education of the Patient's Muscular Sense as to an Erect or Improved Position.—A great many crooked patients, when told to stand up straight, place themselves in a worse position than before. Their muscular sense has become so perverted that the vicious posture appears to them quite natural, while the improved position in which they are put by the surgeon appears to them, through their perverted muscular sense, to be totally incorrect. This re-education is carried out coincidentally with the exercises; while the patient is performing an exercise she assumes the "best possible position," and in the intervals between the exercises she is encouraged to maintain it. After a time this "best possible position" becomes habitual, and the strengthened muscles enable her to maintain it always. This brings me to

The Improved Position to be Maintained at all Times.—It is not at all sufficient to give the patient treatment every day for half an hour, and then to let her return home to sit and stand and walk in the same old bad position until the next visit for treatment on the following day. Measures must be adopted to ensure as far as possible that *correct* postures are assumed. Besides precautions as to position in writing, the patient should not stand at lessons, should always have a back at the right height and shape to lean against, and should never be allowed to remain in a bad position if it can be helped. The parents have got to assist in this matter and to continually keep an eye on the patient, at least for the first few weeks. As an example of the way in which the surgeon's influence is kept up at home, I may mention that all patients are required to place themselves against the door for a few seconds in the "best possible position" before and after every meal; a mark-book is kept in which the patient records by a stroke that she remembered to do this by herself, or by a nought that she had to be reminded. This is known as "meal-standing."

Attention to General Health.—Patients are encouraged to take plenty of outdoor exercise, walking, cycling, tennis, etc., to eat plenty of food—they are weighed every fortnight—and to have plenty of sleep.

Subsequent Home Treatment to prevent relapse in the improvement or cure that has been obtained by the surgeon.—To continue to enlist the patient's interest and co-operation in her own case, she is given a "home prescription" of exercises to be done for half an hour twice daily for six months, and then once daily for another six months. She is then examined again, and if there is no relapse, a shortened home prescription is done for twenty minutes daily for another two years. In all cases it is essential to persevere in the maintenance of good positions until growth has ceased.

RESULTS OF THE TREATMENT BY POSTURE AND EXERCISE.

From a critical examination I have made (5) of the notes of 1,000 cases of scoliosis treated on these principles, and every day confirmed by my own observations and experience, I know that in over 83 per cent. a permanent cure is obtained, and that in 94½ per cent. increase of structural deformity is entirely arrested.

Such results should surely be sufficient to induce other members of the profession to give this well-established method a trial, especially as from all quarters we hear of the unfavourable results of other and older methods, and of attempts to introduce new ones. Why will they not do so? I fear it is for two reasons: one is that they have been educated to regard treatment by exercises for any ailment as outside their province, and hardly worthy of their personal attention; and the second, that they fear the treatment may be monotonous and take up too much time. And so the work which should be done by them is handed over to be done by a masseur. After many months they are unable to observe any improvement, and so they apply a support or a so-called corrective jacket, while gymnastic treatment falls still further into disrepute.

I look forward to the time when all forcible and mechanical methods will be things of the past, and every orthopædic surgeon will be treating these cases by "posture and exercise" much in the manner I have here outlined.

INDICATIONS FROM THE URINE IN TREATMENT OF CERTAIN DISEASES OF THE SKIN. (*a*)

By L. DUNCAN BULKLEY, A.M., M.D.,
Physician to the New York Skin and Cancer Hospital, Consulting Physician to the New York Hospital, &c.

THE urine is a very complex fluid, and reflects the condition of the system from day to day, to a surprising degree and in a manner which is not realised as fully as it should be. If subjected to an absolutely critical analysis of every possible ingredient, it is probable that no two specimens of urine passed by the same individual at intervals of some hours would be exactly alike, as has been shown by many observers, since the publication of the remarkable lectures of Dr. Bence Jones nearly fifty years ago (*b*); it was this book which first seriously directed my attention to the intimate relations between the condition of the urine and various systemic changes.

It is not difficult to appreciate how or why the urine may furnish valuable indications in regard to the treatment of certain diseases of the skin when we recall the anatomical and physiological relations of the kidneys to the system. As I have remarked on another occasion (*c*), "After the blood has received the elements of nutrition from the stomach and intestines, and has been prepared and modified by the various organs, including the internal secretions, it also receives excrementitious substances from the tissues, largely through the lymphatic system. Then, after it has been aerated and purified by the lungs, and is on its way through the aorta to nourish the body, a small artery takes, as it were, a sample of this arterial blood to each kidney for final judgment as to its quality and for the removal from it of injurious substances, as far as possible; this relatively small portion of purified blood is then returned to the vena cava and thus again to the lungs, for further oxidation. It is to be remembered that only a relatively small portion of the blood flows at one time through the kidney (even under forced diuresis it is estimated

that only one-twentieth of the blood passes through the kidneys in a minute), while the great bulk of it passes unchanged directly to nourish the brain and the rest of the body, waiting for its further purification by the kidneys. These organs might, therefore, be spoken of as the final judges of what perfect blood should be, as their function is to eliminate substances injurious to the body."

The urine, therefore, is the most perfect exponent of the catabolism and anabolism of the system, and too much stress cannot be laid upon the importance of its repeated and complete volumetric analysis in connection with the treatment of very many cases of diseases of the skin; for by it we may learn, daily if we will, much which cannot be otherwise ascertained in regard to the manner in which the nutritive processes are carried out, and the character of the blood which induces the cutaneous disorder.

It is understood, of course, that our study relates to the results of *functional derangements* of the urinary secretion, and not to evidences of organic disease of the kidneys; for albumen and casts, and even glycosuria, play but little part in the urinary changes which we are considering. On the contrary, very many of the abnormal conditions of the urine to be considered later have very little if anything to do with the integrity of the kidneys, but rather represent a failure in some portion of the system to elaborate perfect blood, and they would rather indicate a proper and faithful performance of kidney functions, in attempting to remedy a faulty blood state, and remove injurious elements.

These abnormal conditions, then, relate to volumetric derangements in the many constituents of urine which might ordinarily be considered normal, but which under minute analysis is often found to be in one way or another quite different from the standard of that belonging to perfect health. This is so constantly found to be the case among the thousands of analyses which have long been made in my laboratory in connection with private patients, exhibiting many different cutaneous ailments, that for years I have leaned very heavily on my repeated quantitative urinary analyses, in different cases, for guidance in regard to the proper internal measures required. In this brief paper I cannot attempt to analyse the mass of data collected, but I would like to so strongly impress the practical teaching that I have had from them that others will be inclined both to study the subject and also to reap the benefit which I have obtained in practice, from a close consideration of the urine in its relation to certain diseases of the skin. For this purpose I have had collected the data from some three thousand (2,952) analyses made in my laboratory since 1909, and will utilise them as best I may in the brief time at my disposal. The analyses have been made according to Purdy (*a*), and his percentages have been used.

It is recognised, of course, that the condition or composition of the urine may be influenced greatly at any time by the character and quantity of the food and drink consumed, also by the amount of oxygen inhaled, by physical and mental exercise, and by the action of various organs, etc., etc.; therefore in estimating the importance of any particular change found in its composition, much thought and care must be exercised in order to interpret correctly the significance or bearings of the same upon the conditions present, whether it be on the skin or any portion of the body, and to apply the proper remedies, whether dietetic, hygienic, or medicinal.

In general medicine the relation between the skin and the excretion from the kidneys is a matter of everyday observation and consideration. Thus, all are familiar with the temporary changes which may take place in the urine from a chilling of the surface, in fever, before and after an attack of gout, etc., as also with the dry, parched skin in chronic Bright's disease and glycosuria, likewise with the relief afforded to congested kidneys by a free diaphoresis, &c., &c. But we have been slow to recognise the relation of deficient or deranged kidney excretion to the integrity of the skin, and its functions, although occasionally very strong evidence of this has been adduced by individual observers, which we cannot here dwell upon.

Unquestionably much of the failure to utilise the indications from the urine in the treatment of certain diseases of the skin has been due to the too prevalent inclination to regard all cutaneous affections as purely local conditions, or idiopathic diseases, in which the skin is alone concerned, and as due to external causes or of parasitic origin.

While I recognise fully the influence of microbic agencies in connection with very many diseases of the skin and of other organs, I also claim that it is very short-sighted to disregard, as is often done, the soil, or physical condition of the individual tissue in which the micro-organism lodges and finds its nourishment. Certainly in many lines the pendulum of medical thought, if not practice, is swinging away from a purely local ætiology to a recognition and study of the constitutional relations of disease; thus, in tuberculosis we are slowly coming back to recognise the truth of the teaching of Sir Andrew Clark who many years ago used to say: "Gentlemen, do not pay so much attention to the lungs; take care of the stomach and the lungs will take care of themselves," and even in cancer there is a strong tendency to regard the perversion of cell growth as due to faulty metabolism, principally of protein elements.

It is high time, therefore, for the dermatological world to review its basis of thought, and, if necessary, to revise its method of procedure, in regard to the care of many of the lesions on the skin which may require treatment. Sir William Osler has rendered great service by his careful and intelligent work along certain dermatological lines, in regard to the connection of skin lesions with internal disorders, thus showing the direction toward which studies should be made if we are to arrive at a true conception of many cutaneous affections and their cause.

In the clinical study of the urine observers of late years have commonly dwelt on the importance of making only tests of the entire urinary output of the day, insisting that percentages signify nothing, unless they relate to the whole amount of urine passed in the twenty-four hours. While I grant that this is often very important, and while in many cases I have the entire daily urine saved and measured frequently, even over long periods of time, and samples of the same analysed, in the majority of cases I find greater benefit from the older method of analysing that passed at bedtime, or at 10 o'clock, and that passed in the morning, or at 7 o'clock; in this way we get a separate estimate of the result of the work and food of the day, the *urinum cibi* of older writers, and that passed after rest and fasting, the *urinum haustus*. The contrast between the two is often surprising, and by adding the figures from each and dividing the result, we can get a very fair idea of the character of the total output. Bouchard, (*a*) who remarks, "We are only on the threshold of discoveries which remain yet to be made in the chemical analysis of the urine," has made some interesting experimental studies on the toxicity of the urine, which are very instructive. He summarises one part of his studies as follows: "What is certain is, that during the day the body forms a substance which, when accumulated would induce sleep, and that during sleep it elaborates, instead of this narcotic substance, a convulsive substance which, when accumulated, could produce muscular twitchings and induce waking." He had previously shown experimentally that a concentration of the day urine, when injected into animals, in sufficient quantity for their weight, caused death by coma, while a concentrated night urine caused death by convulsions. This subject is a most interesting one, which cannot be gone into now, but this much is given in order to support the view that the analysis of different portions of the urine, taken at various times a day can often yield important and valuable data in

regard to the functioning of different parts of the organism and the nutrition of the system, including the skin.

Quantity.—The actual quantity of the urine passed each twenty-four hours may, of course, vary greatly according to the action of the skin and lungs, and the quantity of fluid taken into the system; but we all know that there is a general average quantity which should be passed in health, about 45 ozs. for a person of 150 lbs., while in diabetes and various forms of kidney disease the normal quantity may be enormously increased or diminished, as also in certain nervous states. Few realise, however, that with only functional derangement of the system the daily quantity may vary very greatly, as I have watched it in many patients with skin ailments. Thus, in a lady, weighing 160 lbs., with lichen planus, I have had the urine measured almost daily for many weeks, and in the weekly record it will sometimes run over 70 ozs., and perhaps the next day only 34 ozs. Another lady, weighing 163 lbs., with severe psoriasis, passed but 13 ozs. on the day before her visit, and on other days had passed 11 and even as little as 7 ozs. of urine in the 24 hours; and many instances could be given where there was very imperfect and deficient urinary secretion in those who supposed they were in good health, except for the eruption.

Specific gravity.—While, as a rule, the specific gravity of urine is supposed to depend upon the quantity passed, and this again largely upon the amount of fluid taken into the system, this is by no means the universal rule, for it may vary at times very greatly according to the state of the system. Thus, I have found it 1.041, with no sugar, and as low as 1.001, with no actual kidney disease. And it is just this variation in the quantity and specific gravity of the urine from time to time which, if quickly recognised and intelligently interpreted, will aid much in understanding the systemic and metabolic disturbances upon which many diseases of the skin depend. And as these wrong conditions of the urine are corrected by appropriate treatment, dietary and medicinal, an eruption which had previously proved rebellious will yield favourably to local measures which had before seemed ineffective; this, of course, applies mainly to such dernatoses as eczema, psoriasis, acne, lichen planus, urticaria, some bullous eruptions, &c.

Volumetric acidity.—Closely associated with the quantity and specific gravity of the urine, and of even greater importance as a guide in connection with the treatment of certain diseases of the skin, is the actual volumetric acidity frequently measured, which can be done quite easily by the oxalic acid and phenolphthalein test.

Bearing well in mind what was previously said in regard to the formation of the urine directly from the completed arterial blood, on its way to vitalise all the tissues of the body, it can readily be understood what an important indicator this excretion is in determining the exact state of the blood, both as to its excrementitious substances and its alkalinity. With a standard of about .300 for the average acidity of normal urine, it must certainly make a great difference in regard to the wellbeing of the individual, as well as in the condition of the skin, when the acidity is found to be .600 or .800, or even 1.386, as I recently found it in a very bad case of inducted acne; or when it is reduced to .126 or even .063, or when it is even strongly alkaline, and that without bladder complications.

Excessive urinary acidity is frequently observed in connection with many diseases of the skin, eczema, lichen planus, psoriasis, acne, and others, and eruptions will often be seen to be red and congested and the itching increased when there is high acidity of the urine, and to be relieved when this is reduced by appropriate treatment; for the abnormal acidity of the urine but reflects a lessened alkalinity of the blood circulating through the skin. On the other hand, a greatly reduced acidity of the urine, or persistent alkalinity, not dependent on bladder trouble, may be quite as harmful; and I recall a case of urticaria which proved rebellious, until on analysis of the urine I found it to be .063, almost neutral, when the eruption was arrested promptly on the free administration of urotropin, bringing the acidity of the urine up to normal.

Urea.—As the principal end product of the metabolism of protein substances, urea, or its proper excretion, may be of great importance in connection with certain diseases of the skin. In perfect health, with a mixed diet, the urea should be pretty constant at 2 per cent. in the urine, and nearly an ounce should be passed each day. But careful analysis in many patients with certain skin affections shows the greatest variations, from two or three times the normal amount down to an almost total absence of urea, indicating extremes of deranged nitrogenous metabolism. In a case of dermatitis herpetiformis, Hardouin (*a*) made a daily analysis of the urine of 24 hours, over a period of six months, and found that on eight occasions, at pretty regular intervals, there was a fresh eruption after a period of diminished excretion of urea; the outbreak began a few days after the lowest point of urea elimination was reached. In a second case the onset of the attack also coincided with the lowest point of urea excretion; this has been verified by others, and also in a case in the New York Skin and Cancer Hospital.

Uric Acid.—In spite of the professional discredit into which uric acid itself, as a factor in disease, has fallen, there is little question but that the work of Haig (*b*) has served a good purpose in directing attention to the harmful results of a faulty metabolism of nitrogenous products. While its accurate quantitative estimation in the urine is difficult, it happens that sometimes the indications from its excretion are very suggestive.

Thus, in my own personal case, as already reported (*c*), the uric acid and urea in the urine were actually higher after a five days' experience with a non-protein diet of rice, bread, butter, and water, than they were on the night and morning before this was undertaken; showing that without the introduction of any exogenous protein or nuclein the blood took up from the tissues effete nitrogenous elements, and made them to appear in the urine, even in a greater degree than before. With this relief to the system the extremely distressing vesiculo-bullous eruption on the hands, to which I had been subject for a good many years in the summer, often lasting many weeks, disappeared completely by the expiration of this five days' strenuous diet, without the use of any remedies, internal or external. I may add that the same experience has been repeated in myself with the recurrence of the eruption in summer three or four times.

Indican.—The ætiological significance of an excess of indican in the urine has not as yet been clearly worked out, but it is being recognised more and more as a valuable indicator of putrefactive changes occurring in proteids, mainly in the large intestine. It is interesting to observe, however, how frequently it appears in the urine in connection with outbreaks of eczema, urticaria, acne, and some other skin affections, and how they will improve under the same local treatment when this urinary error is removed by appropriate measures, dietary and other. As far as I know no satisfactory explanation has been given as to how the putrefactive changes in the intestine affect the skin, but intestinal auto-intoxication is a factor which has to be considered and overcome, in connection with many affections of the skin, and the variations in the amount of indican in the urine afford a most satisfactory means of determining the existence of this condition.

Sulphates.—These, like indican, may often prove a good indicator of the proper metabolism of proteid substances, and they may sometimes be present in

---

(*b*) Haig, Alexander. "Uric Acid as a Factor in the Causation of Disease," London.

(*c*) Bulkley, "Personal Experience with a Very Restricted Diet (Rice) in Acute Inflammatory Disease of the Skin." *Medical Record*, January 28th, 1911.

excessive quantity even when no indican is found. While the normal standard here accepted is 1 per cent., we have frequently found it 2, 4, 6, and even as high as 22 per cent., especially in psoriasis; this would indicate an intake of nitrogenous matter far beyond the demands of the system or the power of its proper assimilation.

Chlorides.—The estimation of the chlorides in the urine sometimes affords suggestions of value in regard to the treatment of certain cutaneous affections, and while a moderate excess or diminution from the average has no great significance, being derived from the food, a great excess often indicates that the individual consumes more food than the system requires, while a great diminution may signify the need of increased nutritive matter. Among our analyses, in one case, that of a young lady, æt. 20, with psoriasis, there was 50 per cent. of chlorides, and in a lady æt. 60, with eczema, there was but 2 per cent. The immense importance of chloride of sodium in the economy, in its relation to the gastric secretion, blood, and tissues, would imply that a knowledge, through the urine, of its supply in the blood and its proper elimination must be of value in connection with disease, whether of the skin or other portions of the body; and our practical experience has demonstrated this to be the fact time and again in many skin affections.

Phosphates.—These being also largely derived from the food are subject to considerable fluctuations in the urine in normal persons, and some care is required in judging the results of analysis. But phosphates are known to be largely increased in the urine in certain chronic diseases, as of the bones, nervous tissue, &c., and diminished in many other conditions, and the greatest variations were continually found in our cutaneous cases, in a manner often quite inexplicable. With an accepted average normal standard of 10-12 per cent., there were many specimens in which only a trace was found, while the highest recorded was 26 per cent. Continued increased elimination will often indicate a waste of nervous tissue, which may be of the utmost importance in some dermatoses: while with a prolonged greatly diminished excretion we have a failure of nutritive powers which is of equal importance in other skin affections.

There are other ingredients of the urine, normal and abnormal, which have not been so fully studied, but which may be of importance in some conditions of the skin; such are the colouring matter, which has been shown by Bouchard to be poisonous, creatinin, skatol, acetone, β-oxybutyric acid, &c. The thought naturally arises that if derangement in some of the urinary elements which have been carefully observed is so important in connection with certain diseases of the skin, can it not be possible that some of these other ingredients of the urine may by their derangement, act in the same or different manner, in inducing some of the skin lesions which are often so troublesome?

There are yet a few urinary changes observed microscopically which should be mentioned as affording indications for treatment in certain diseases of the skin.

Urates and Uric Acid.—Heretofore we have spoken of uric acid as determined by quantitative analysis, but in many cases it will be grossly represented by masses of urates or even uric acid crystals soon after passing. These are always of some significance in connection with certain skin affections, but should be carefully interpreted; for, like the uric acid showers after attacks of gout, they may represent the effort of nature to throw off accumulated, effete, nitrogenous matter. When such deposits persist they indicate perverted nitrogenous metabolism, which should be attended to quite as much as other urinary derangements, if the best results are to be obtained in eczema, psoriasis, acne, and other affections.

Oxalates.—Oxalate of lime was formerly regarded as of much more importance, as a urinary deposit, than it is at present, for it is now recognised that it may come from an excess of certain vegetables and fruits in the diet. But when excessive or persistent it signifies a process or state of sub-oxidation which should not be neglected in connection with certain affections of the skin. Thus, in acute lichen planus and pruritus ani, oxaluria is an indication for the free administration of nitric acid, which will often prove of the most signal value in these troubles.

It would be interesting and highly instructive and profitable if we could point more specifically to changes in the urine which necessarily accompanied definite diseases of the skin. But, unfortunately, this is not possible in our present state of knowledge; we must have vastly more carefully recorded observations. Undoubtedly many have the alterations in the urine which we have mentioned, with no eruption, but the same may be said in regard to many diseases of other organs; no one doubts the connection between uratic deposits and true gout, and yet the former are continually found without the latter. Xanthoma diabeticorum is recognised as associated with and probably dependent upon glycosuria, and yet how exceedingly rare it is in diabetes. There are undoubtedly concurrent causes of disease, of which we as yet know but little and it is quite possible that closer observation and analysis will show further changes in the urine, or combinations of changes, which may throw light on the pathogeny of some affections of the skin. In the present communication I have only endeavoured to contribute my mite to this most interesting, instructive and profitable line of investigation, and urge its further elaboration; for, of the practical importance, along therapeutical lines, of the matters which I have presented my daily experience makes me continually more positive.

One more thought. Mention has been made of a number of more or less acute and some chronic cutaneous affections in regard to which functional disturbances in the kidney excretion have been observed to be of significance. Is it not probable, therefore, that careful study will demonstrate the same to be more or less true of still other eruptions which have not thus far been investigated in the direction, and that possibly in most cases where the skin is in any way diseased there may be some metabolic errors, which may be evidenced in the urine, if sufficient time, patience and skill are employed? The notorious rebelliousness and proneness to recur of many affections of the skin should lead dermatologists to look away from a purely local ætiology, and, with a broader view of medicine, seek for the underlying causes, which, as in diseases of other organs, are often found to depend on a defective metabolism, which is commonly indicated by defective or deranged urinary secretion.

SOME ABNORMALITIES IN BREAST MILK AND THEIR TREATMENT.

By HUGH H. RIDDLE, M.D.Cantab.

A constant low fat percentage or a decrease in amount in the nursing mother's milk has generally been considered an unanswerable argument in favour of substituting artificial feeding for Nature's own method, *i.e.*, breast feeding.

However convinced the physician may be of the infinite superiority of breast feeding over bottle feeding as a general rule, a sudden cutting off of the supply or a failure of the infant to make a proper weekly gain in weight in practice usually forces him to the conclusion that, under the special circumstances, a change to bottle feeds (to which the requisite amount of additional cream can be readily added) is not only justifiable but absolutely imperative.

Where a gradual decrease in the supply of mother's milk takes place such measures as increasing the fluids in her diet, ordering more rest, etc., sometimes are efficient. Where there is complete cessation of the flow, however, something more radical is needed to stimulate the glandular structures into taking up again their interrupted functional activities.

Where the milk is normal in amount but deficient in fats there are two classic alternatives to resorting to bottle feeding: (1) increasing the nitrogenous elements in the mother's diet while cutting down her exercise, and (2) giving spoonfuls of cow's cream to the infant after or immediately previous to each breast feed.

In actual practice both these alternatives frequently fail to produce the desired effect. The commonest result of the "stuffing" treatment of the mother is a digestive upset which is frequently the end of all attempts at nursing her baby, while the spoon feeds with cream often lead to undue sickness in the infant, with the appearance of curds and numerous small fat particles in the stools.

Tables I. and II. below give the results of a series of experiments carried out in the past six months at the Queen Charlotte's Hospital with a preparation known as Lactagol, which is claimed to act as a direct galactogogue, increasing both the amount of milk and the fat ratio.

To Dr. Arthur Stabb, Physician to Queen Charlotte's, I am indebted for the facilities allowed me for observing in the wards a number of his own patients under lactagol and for recourse to his case notes. In the series of observations on out-patients I have to thank Dr. J. B. Banister for his invaluable assistance in carrying out the analyses in the Queen Charlotte's laboratory

Lactagol is a dry extract of cotton seed containing the active constituents of the seed in a concentrated form. For increasing the amount of milk secreted or raising to the normal a deficient fat ratio it was given in teaspoonful doses in milk three times a day.

The subjects of the first experiment (Table I.) were taken in sequence from the in-patients at Queen Charlotte's, the only common characteristic being a low fat ratio. The analyses were made in the Queen Charlotte's Pathological Laboratories :—

TABLE I.

Case No.	Date of 1st Analysis.	Fat Percentage.	Time on Lactagol.	Fat percentage at 2nd Analysis.	Fat Increase.
1	4th day	1.8	7 days	2.8	1.0
2	4th ,,	1.6	7 ,,	3.0	1.4
3	5th ,,	1.8	7 ,,	2.8	1.0
4	5th ,,	2.4	7 ,,	3.4	1.0
5	5th ,,	2.6	7 ,,	3.6	1.0
6	5th ,,	2.0	7 ,,	3.8	1.8
7	5th ,,	2.2	10 ,,	2.6	.4
8	5th ,,	2.2	5 ,,	3.0	.8
9	5th ,,	1.9	7 ,,	3.4	1.5
10	5th ,,	2.2	7 ,,	3.0	.8
11	5th ,,	2.8	7 ,,	3.6	.8

Carter and Richardson in 94 samples of breast milk examined found an average of 3.07 per cent. of fat in the early months of lactation. The average for these 11 cases after the lactagol is 3.18 per cent.

The second table shows the results when the lactagol was given not at the beginning of the lactation but at anything from two to four weeks after the birth of the infant. The mothers here, after samples of their milk were taken for preliminary analysis, were given supplies of lactagol to take at their homes. After the week's supply had been used up they returned to the hospital for the second analysis of the milk :—

TABLE II.

Case No.	Day of 1st Analysis.	Fat Percentage.	Time on Lactagol.	Fat percentage at 2nd Analysis.	Fat Increase.
12	21st day	2.8	7 days	2.8	—
13	24th ,,	3.2	7 ,,	3.4	.2
14	19th ,,	2.4	7 ,,	3.6	1.2
15	28th ,,	3.6	7 ,,	3.6	—
16	15th ,,	2.8	7 ,,	3.8	1.0
17	18th ,,	3.6	7 ,,	4.0	.4
18	10th ,,	3.0	7 ,,	3.8	.8
19	14th ,,	3.2	7 ,,	3.0	.2
20	14th ,,	1.8	7 ,,	3.2	1.4
21	13th ,,	2.0	7 ,,	3.6	1.6
22	12th ,,	2.2	7 ,,	3.8	1.6

In those cases, such as numbers 13 and 15, in which the fat percentage was about normal (3.2 and 3.6 respectively) at the start of the taking of the lactagol the increase was slight or none at all. On the other hand, those mothers whose milk showed a serious deficiency in fat (as for example Nos. 20, 21 and 22) showed a marked rise in the fat ratio after the week's taking. The average fat percentage of the milk of these 11 cases (which were not selected, but were the whole number who could be induced conscientiously to carry out the treatment and to report themselves for analysis) was, at the finish of the week's course of lactagol, something over 3.5, against Carter and Richardson's average of 3.07. In addition to the above series of trials on the twenty-two cases taken in sequence, lactagol was also given in a number of special cases both in private practice and at Queen Charlotte's, in which the milk was either deficient in quantity or patently poor in quality as shown both by analyses and by the failure of the infant properly to gain weight.

Case 1 (private), Mrs. E. S., primipara, æt. 22, twin girls, premature (7½ months). Milk secretion began on fourth day. Normal in amount on sixth. On seventh began to lessen. On ninth was unable to get even a half-ounce of milk with breast-pump for analysis. Babies put on bottles plus breast feeds every two hours. On tenth day one ounce milk obtained by breast-pump. Analysis showed 1.4 per cent. of fat. Mother put on lactagol same evening. By next evening (11th day) after four doses of lactagol breasts full and milk oozing. Each infant satisfied with two hour breast feeds from then on till time of writing (6th week). Second analysis on nineteenth day, after ten days of lactagol, showed fat percentage of 3.6.

Case 2 (private), primipara, æt. 26, premature infant, eighth month, mother an alcoholic, wife of an innkeeper. Milk normal in quality and amount until twenty-first day, when it suddenly ceased. Cessation of milk roughly coincided with the mothers' return to her duties behind the bar. Infant immediately put on bottle. As the infant failed to thrive on artificial feeding, the mother on the fourth day after cessation of her milk was put on lactagol. After the third dose the milk reappeared and, on the third day of taking, the bottles were given up entirely. The infant was breast fed exclusively from then on until the eighth month. The lactagol was taken for periods of two or three weeks with fortnight intermissions from the second to the seventh month.

Case III. (Queen Charlotte's), I.C., æt. 25, primipara. This case instances well the rapid action of lactagol in cases where from the start the milk has been deficient in quantity. The infant had a harelip utterly preventing suckling. From the start the milk has been drawn off with a breast pump.

On the fourth day attempts were made by the nurse at two hour intervals to draw off milk, but not more than three or four drachms could be obtained. On the fifth day the flow not improving the patient was placed on lactagol. On the sixth day and from then on until discharge the nurse had no difficulty in drawing off from an ounce-and-a-half to two ounces at each feeding time. A special feature of interest here was that the drying up of the milk which not infrequently follows when the breast pump must be continuously used instead of natural suckling apparently had no effect in curtailing the flow.

Case IV. (Queen Charlotte's), E.F., æt. 36, twins. This woman, a healthy multipara, had had ten children previously. The first six she had had no difficulty in nursing to full nine months. The next four had been each nursed for three weeks or a month, after which bottle feeding had to be resorted to. The twins weighed respectively 5 lbs. 12½ ozs. and 6 lbs. 3 ozs. at birth. After the normal loss in weight occurring in the first three days the small quantity of milk observable in the breasts on the fourth day and fifth day suggested the advisability of giving lactagol. The patient was ordered a teaspoonful three times a day. On the seventh day both infants had regained their birthweight, and from thence on kept up a steady gain.

Instead of following the ordinary procedure of alternating breast feeding with bottle feedings, the mother for the three weeks she was in the hospital was able to give each infant the breast every two hours without any apparent strain on her own system and with most beneficial results to the two infants.

Case A. G., æt. 31, primipara. Cæsarian section. Here the lactagol was given as a precaution against any scarcity of milk which might result from the shock of the abnormal method of birth, and because of the relatively greater value of what will probably prove to be the mother's only child. An abnormal loss of weight occurring the first three days (8 ozs.) also suggested the use of the lactagol. A mixture of one part cream to three parts water and two or three bottles a day were also given in addition to the breast feeding. The lactagol was begun on the fourth day.

	Weight.			Weight.	
Day.	lbs.	ozs.	Day.	lbs.	ozs.
1 ..	7	4	8 ..	7	4
2 ..	7	1	9 ..	7	6
3 ..	6	12	10 ..	7	7
4 ..	6	13	11 ..	7	9
5 ..	6	15	12 ..	7	11
6 ..	7	0	13 ..	7	12
7 ..	7	2	14 ..	7	13

On the mother's discharge on the twenty-third day the infant weighed 8 lbs. 10 ozs.

Ethel Pigeon, æt. 34, fourth child. The mother had not been able to nurse any of her previous children on account of lack of milk. After the birth of the present baby there were no signs whatever of milk on the fifth day. Lactagol was given in teaspoonful doses in milk and within twenty-four hours the secretion began, the mother nursing the baby comfortably at the time of discharge from hospital. On examination the breasts were well-rounded and firm, large but not fat, with well-formed nipples, in short the typical healthy breast of the normal nursing mother.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Radical Cure of Hydrocele.—Mr. Willmott Evans operated on a case of hydrocele. The patient was 37 years of age, and for the last twelve years he had suffered from hydrocele of the left testis. It had been tapped many times, but the fluid had always re-accumulated, and in the summer time the size of the swelling grew very troublesome, and he wished to have it permanently cured. The diagnosis was simple: fluctuating swelling in the scrotum almost surrounding the testis and translucent to light.

The patient was anæsthetised. Mr. Evans swabbed the skin of the scrotum with acetone and then with a 2 per cent. solution of iodine. Then he made an incision at the upper part of the scrotum over the pubic crest; it was about two inches in length. The assistant then pressed the swelling upwards towards the incision, and the glistening parietal wall of the tunica vaginalis was seen. It was seized with forceps and a small opening was made in it, through which the contents escaped; it consisted of straw-coloured hydrocele fluid of the usual kind. The empty sac was drawn through the opening and examined, and the parietal wall of the tunica vaginalis was found to be distinctly thickened. With scissors the greater part of the parietal layer of the tunica vaginalis was then cut away, only a small portion being left close to the testis. During this, great care was taken to prevent any injury to the vas deferens. All bleeding vessels were tied and the testis was returned into the scrotum. Silk sutures were inserted and a gauze dressing applied.

Mr. Evans said that in a few cases a hydrocele effusion will disappear spontaneously. This is the case especially in infants, in whom tapping is rarely required. In some other cases, especially where the hydrocele is the result of a definite trauma, a single tapping is sufficient for a permanent cure; but in most cases of hydrocele it will be found necessary to continue the tapping indefinitely as often as the fluid re-collects sufficiently to prove troublesome. In elderly and old people who do not lead active lives, and who may not be in sound health, it is probably best to recommend tapping at intervals of six months or so rather than to advise the patient to incur the risks of an operation. In a certain proportion of cases the injection of liquids into the sac may suffice for a cure, but it is impossible to guarantee in any individual case that this method will be effective; still, it has its uses, and may well be employed where the patient refuses to submit to radical cure. Several methods have been employed for curing radically a hydrocele, but that used in this case was in his opinion the best. The accumulation of fluid in the cavity of the tunica vaginalis is due to a disturbance of the equilibrium between secretion and absorption: in health the tunica vaginalis is always secreting serum to lubricate the surface of the testis and to prevent friction between it and the skin, but the amount of serum secreted is almost exactly balanced by the amount absorbed, so the quantity remaining in the cavity is very small. In hydrocele this equilibrium is upset: either the amount secreted is increased or the amount absorbed is diminished, or both these factors may act at the same time, with the result that hydrocele fluid accumulates in the cavity. In the operation that had just been performed two things had been done: by the removal of almost the whole of the parietal layer of the tunica vaginalis the secreting area had been greatly reduced, so that the amount of fluid secreted was greatly reduced, and at the same time the removal of the parietal layer had thrown the cavity of the tunica vaginalis into free communication with all the numerous lymphatic spaces of the scrotum. In this way not only is the secreting area much diminished, but the absorption area is vastly increased, so that the equilibrium between secretion and absorption is re-established. There is one other important point—where should the incision be placed? It is on the whole better to put it as high as possible, where it is less likely to get contaminated and where the character of the skin makes disinfection more thorough. It may be perhaps as well to mention, he said, that very thorough hæmostasis is desirable, as the loose connective tissue of the scrotum lends itself readily to the formation of a hæmatoma.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Section of Ophthalmology.

Meeting held Wednesday, December 3rd, 1913.

The President, Sir Anderson Critchett, Bart., C.V.O., in the Chair.

Mr. Cole Marshall showed a case of "staphyloma posticum verum."

Mr. Leslie Paton two cases of "rodent ulcer" treated with CO_2.

Mr. Macnab a case of "infiltration in and around the iris."

Mr. Grimsdale a case of "microphthalmos."

GLASS-WORKER'S CATARACT.

Mr. Herbert Parsons showed specimens of experimental glasses prepared by Sir William Crookes, O.M., P.R.S. They were synthetically prepared glasses. Sir William Crookes had two soda fluxes made by Messrs. Powell, and added to these specimens of flux, certain metals in definite proportions. He then made the glasses in small quantity, cut slices, polished them, and investigated their properties in reference to transmission of heat, and he had taken photographs of the absorption of ultra-violet rays with a quartz spectrograph to test their transmission of luminous rays, and estimated their colour with the tintometer. In order to test with the greatest possible delicacy, Sir William invented an exceedingly delicate instrument named the radiometer balance. He made a glass which cut off 96 per cent. of the heat. The subject was of much wider importance and applicability than the research seemed at first to show.

Dr. Morrison Legge, of the Home Office, spoke at considerable length on the subject. He said glass-worker's cataract was brought to his notice as a member of the Departmental Committee which sat to inquire into the question of compensation for industrial diseases, in 1906; and much valuable information was forthcoming from a very intelligent secretary of a glass-workers' association. The late Mr. Simeon Snell set himself to collect information on the subject, but his method was not calculated to yield the truest results, for he circularised the manufacturers themselves, asking how many cases of cataract they had known among their workers. As a result Mr. Snell came to the conclusion that cataract was not specially prevalent among glass-workers. A systematic examination of workers for the condition might result in men having the condition being discharged, whereas it took ten to twelve years to prove disabling. He, Dr. Legge, went himself into the glass factories of St. Helens and Sunderland, and he was very much impressed by the number of men who came up showing this cortical cataract, varying in size from a pin's head to what looked like a large blot of ink in the centre of the pupil; it was quite different from the peripheral striæ in senile cataract. He was struck by the small degree to which the eyesight of the patients suffered. In only very few cases were there opacities in the cornea.

The President, in thanking Dr. Legge for attending and making his valuable contribution, said that in Italian glass works the workers were much nearer the flame, and it was very rare indeed to find a worker of forty years of age whose cornea was not affected.

Mr. N. Bishop Harman read a contribution, and showed photographs, on an

OPERATION TO IMPROVE THE EFFECT OF AN ARTIFICIAL EYE.

His object was to render the loss of an eye less conspicuous. He remarked that, other things being equal, the effectiveness of the disguise was controlled by the shape of the palpebral fissure. With a small fissure, the shell was effective; with a wide and generous form of fissure the shell provided insufficient support, so that the lids dropped away, deep sulci marked the lids, and the shell was exposed in its naked bareness. The operation aimed at doing for the large-eyed what the small-eyed had by nature. The lids were secured in a clamp devised for the purpose, then split at the inter-marginal space, and the raw surfaces brought together so as to shorten the fissure. The lid surfaces were protected from scarring by the suture, by rubber guards that also afforded elastic pressure. On the fourth day the suture was removed and any adjustment of an excessive effect could be made. The effect of the narrowing of the fissure was to draw forward the lids, slightly cover the shell, and shadow it, so that in place of the fixed stare there was a slight and subtle wink. The pull of the lids against each other tended to smooth out the deep sulci above and below; the relative movement of the shell was also improved. The effect was to make the beholder of the face concentrate on the natural eye, which became the fixative feature of the face. In the words of an early poet, it became a face "with one suspicious and one drooping eye"; the slightly winking, drooping eye was a companion inconspicuous by reason of its lesser character.

Mr. W. M. Beaumont read a paper on iritis, rheumatic and toxæmic. He said doubts had been thrown upon the existence of a rheumatic form of iritis, and modern views of the nature of rheumatism seemed to coincide with those doubts. The author, earlier, had been a sceptic, and his views had found expression on several occasions in the columns of the *British Medical Journal*. Poynton's and Paine's invaluable researches, based on bacterial experiment, had stimulated interest, whilst the papers read at the annual meeting of the British Medical Association and at the International Medical Congress brought the subject again to the front. A difficulty arose in Poynton and Paine's results because iritis associated with acute rheumatism was so extremely rare that it might be considered negligible; whereas these investigators had been able, on at least two occasions, to produce iritis by the intravenous injection of the products of rheumatic infection into rabbits. A negation of rheumatic iritis seemed to be a natural corollary of the "passing" of rheumatism, and it seemed to the author that their experiments almost proved too much. He thought that a more extended view of the frequency of toxæmia, and especially of gonorrhœa, as a cause of iritis, would be the outcome of further research. But as, in the past, it had been usual to parcel out the different causes of iritis, without including toxæmia as one of them, it was clear that if that factor were generally accepted, it must very considerably reduce the percentage of some of the fully recognised causes. He thought that the class that would be materially reduced would be the nondescript one "rheumatic."

The paper was discussed by Mr. Lawford, Mr. Herbert Fisher, Mr. Cobbledick, Mr. Mayou, Dr. Thompson, and the President, and the author replied.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held December 3rd, 1913.

Prof. Russell, Vice-President, in the Chair.

Dr. Claude B. Ker opened discussion on

ISOLATION AND QUARANTINE PERIODS IN THE MORE COMMON INFECTIOUS DISEASES.

A full abstract of the author's paper on the subject will be found in another column under the heading of "Original Papers." In the discussion that followed,

Dr. Melville Dunlop said that the matter of infectivity and quarantine periods was of great importance both to the profession and the public. The regulations regarding schools were very diverse, and some of them were very difficult to understand. If all the rules were abolished he doubted if the results would be very different. Sir Henry Littlejohn had told him that the crowded district round the old fever hospital in Edinburgh was the most free from fever of all parts of the town. He agreed with Dr. Ker in thinking that the infectivity of measles was entirely during the stage of invasion, and he was in accord with him in regard to its severity as regards mortality and sequelæ. The infectivity of whooping cough ceased with the whoop. The whoop often ceased during an attack of pneumonia. Such cases were often admitted to hospital and did not spread infection. The infectivity of chicken-pox might be disregarded altogether. Scarlet fever was now so mild a disease that the difficulty often was to recognise it as a disease at all. He suggested that the Society should appoint a committee to discuss and formulate rules regarding the quarantine periods in infectious disease.

Dr. Meikle said that some information regarding infectious disease in the Edinburgh Board Schools might be of value. The average absence due to infectious disease—cases and contacts—was 4,000 out of a school population of 40,000. Thirty per cent. were due to notifiable diseases. Of the total absence one-quarter were due to measles, one-half to whooping-cough, one-eighth to scarlatina, and one-fortieth to diphtheria. If four weeks were taken as the average duration of absence, that meant a loss of 160,000 attendances, or £400 to £500 in Government grants made on an attendance basis. A relaxation had been made in the case of older pupils in regard to measles, and no ill effects had followed. In non-notifiable diseases they had to rely on hearsay evidence. The difficulty in using incubation periods for education in Board Schools was the unreliability of the parents' statements regarding exposure to infection.

Dr. James said that the rules appeared to be based on the germ theory rather than upon clinical experience. The tremendous drop in infectious disease which took place about 1880 seemed to indicate a change in the type of disease, and their rules required revision accordingly. He quoted statistics of absenteeism from the Merchant Company's Schools, and they all went to show that susceptibility was a more important factor than the germ. In the future a gradual increase in the mildness of disease was to be looked to rather than a stamping out of infection.

Dr. Burn Murdock said that in scarlet fever he felt safe after a contact had remained well for five days. In whooping cough he had never seen infection after the whoop had developed. Measles was not infectious after the rash.

Mr. Ferard, Headmaster of Edinburgh Academy, said that from the headmaster's point of view, infectious disease was an unmitigated nuisance. The only line for him to take was to accept the rules given him and to administer them to the letter. At the same time he felt that these rules were an elaborate locking of the stable door after the steed had been stolen. In such diseases as diphtheria they must take all precautions. A schoolboy might readily hand on the disease to a younger child. On the other hand he might suggest that it was the duty of the schoolmaster to pilot children through attacks of mumps, chicken-pox, and German measles. These diseases were more serious and certainly much more inconvenient when they attacked adults. He would very gladly see all the school regulations regarding infectious disease disappear.

Dr. James Carmichael thought that the certificate of the family doctor was enough to permit a child to attend school after infection. He supported the suggestion that a committee should be appointed.

Dr. James Ritchie said the time was ripe to revise quarantine periods. He felt quite happy about scarlatina contacts after five days, but thought eight should be the quarantine period. He agreed with Dr. Ker about diphtheria. Measles was not infectious after the catarrhal stage, chicken-pox after the crusts were off, nor mumps after the swelling had subsided. He had a difficulty in connection with fomites in scarlet fever.

Dr. Fowler said that in the Royal Hospital for Sick Children they had to obey the rules of the Public Health Department just as much as other people. He thought the incubation period of scarlatina might extend to ten days. He questioned the advisability of trying to prevent young children from taking mumps and chicken-pox. These diseases were more severe in adults. In rubella the question of diagnosis was a difficulty.

It was remitted to the Council of the Society to appoint a committee who should formulate rules in regard to infectivity and quarantine periods.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held in Sheffield, November 21st, 1913.

The President, Dr. W. E. Fothergill (Manchester) in the chair.

Mr. Miles H. Phillips (Sheffield) showed a case of "Peritoneal Implantation of the Ovum." This patient was operated upon for ectopic pregnancy and a bleeding tube removed. A small nodule was noticed under the peritoneum of the pelvic wall and was excised. This proved to be an ovum covered by peritoneum, except in one spot through which the ovum had probably passed.

Mr. W. W. King (Sheffield) read a paper on the

Serum Diagnosis of Pregnancy,

in which he described his *technique* and gave his results of the examination of 50 cases. 25 pregnant patients all gave positive reactions; 5 others in whom the clinical diagnosis of pregnancy is uncertain also gave positive results. Two recent septic abortions were negative. Out of 18 non-pregnant patients, 2 sera digested placental albumen. His results of the question of the specific character of the ferments showed that the serum of pregnant patients would in some cases digest carcinomatous tissue and *vice versa.*

Mr. Miles H. Phillips (Sheffield) showed specimens of "Parasitic Ovarian Dermoid" and "Papillary Ovarian Tumour."

Mr. Favell (Sheffield) showed a specimen of "large fibro-myoma of the vaginal wall."

Dr. Gray Newton (Sheffield) showed a specimen of "tumour of the vulva."

HARVEIAN SOCIETY OF LONDON.

On Thursday, November 27th, 1913, the Harveian Society of London held a discussion on "The Registration of Venereal Diseases," at which the following spoke:—

Dr. T. H. Craig Stevenson, Superintendent of Statistics, Dr. G. Blacker, Dr. Campbell Williams, Dr. A. Maude, Dr. Reginald Dudfield, Medical Officer of Health, Dr. Leonard Guthrie, Dr. J. C. Dunn, and Colonel Scott.

With the exception of Dr. Dudfield, Medical Officer of Health, all the speakers apparently were against registration, as impracticable, unfair, and useless.

Dr. Maude, of Westerham, pointed out that when this suggestion of Government notification was first discussed no indication had been held out that there would be any protection to the medical man, either for breach of confidence or errors of diagnosis.

It is hoped that the discussion will be published in full.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Dec. 6th, 1913.

Cirrhosis of the Liver.

The predominant cause of the cirrhosis of Laennec is alcohol. Tripier, however, demonstrated that alcohol was only the exciting cause, the true cause being tuberculosis. This opinion has been supported by numerous anatomo-pathological examinations and tends to-day to adoption.

As to treatment, says Prof. Pic, of Lyons, the first thing to do is to suppress alcohol in all its forms. The lesions produced by alcoholic impregnation of the liver are of two kinds—cellular and conjunctive, the first leading to hepatic insufficiency, the second to hypertension of the portal system. Hæmorrhage may be a consequence of both these lesions. The medical treatment comprises milk diet, diuretics and opotherapy.

In the pre-ascitic stage the patient may get well provided he has will-power enough to abandon his passion. His drink will be water. After a few days of the milk *régime* he may be allowed eggs and vegetables, but no meat. Where hæmorrhage occurs, due to distension of the portal system, hot sitz baths and warm enemas will be prescribed, and in case of epistaxis the nose will be plugged with absorbent cotton steeped in oxygen water, adrenalin solution, or ferripyrine cotton, while chloride of calcium or serum of the horse will not be omitted. Opotherapy may also be tried (liver extract).

When the ascitic stage is reached, ingestion of fresh pork or veal liver is frequently followed by improvement in the condition of the patient. Six ounces of liver, shredded into vegetable soup, are given each day. If this method is repugnant to the patient, the same amount may be given by the rectum. The liver, cut up into small pieces, is allowed to macerate two hours in cold boiled water, when it is "passed" and given in enema with the yolk of an egg and a few drops of laudanum. The powder of dried liver at the dose of three or four drachms a day is also useful.

Autoseropathy, or the method of Gilbert, of Geneva, has given some success. One or two drachms of the liquid are drawn out with a small syringe, and before completely extracting the needle an oblique movement is given it whereby the ascitic liquid is injected into the neighbouring cellular tissue. The result observed in favourable cases is polyuria, decrease of the liquid, etc.

Diuretics play an important part in cirrhosis with ascites, and may be varied at will. Urea (one ounce daily), calomel (one grain every morning for ten days), cream of tartar.

Cream of tartar, 4 dr.
Syrup, ½ oz.
Water, 6 oz.

A tablespoonful every two hours. Or

Nitrate of potash, ½ dr.
Acetate of potash, ½ dr.
Oxymel of squills, 1 oz.
Inf. of juniper berries, 8 oz.

Lactose or sugar of milk (two or three ounces a day), adonis vernalis and other diuretics.

As to surgical treatment, the most simple operation is that of tapping the liquid, but the operation has to be repeated several times, and finally the patient falls into a state of cachexia and succumbs. Tapping is consequently insufficient to cure alcoholic cirrhosis. Talma and Morison tried to aid the portal circulation by fixation of the mesentery to the abdomen (omentopexia), but with little success, for a patient suffering from cirrhosis cannot, in general, recover; there may be a certain improvement in the symptoms and the evolution of the disease may be retarded, but a cure is impossible.

Revulsives in Consumption.

Revulsives diminish the peri-tuberculous congestion and the bronchial catarrh, favour the absorption of exudations, and have a real action on the seat of the malady.

Tincture of iodine, much employed, acts if only by suggestion on certain localised pains (apex, joints). Linseed meal and mustard have a slow and gentle effect much appreciated by the patients. Dry cupping applied in front in the morning, at the back in the evening, affords a *bien être* in diminishing the dyspnœa and cough. The thermo-cautery is useful in local tuberculosis and chronic pleurisy.

Blisters have also their usefulness. Grancher recommends them in the form of strips three inches long and one inch wide, placed parallel to the clavicle, one in front, the other behind, and left on three hours. Under their influence the number of leucocytes is increased.

Cold water (60° F.) is a very active revulsive; it is also antithermic. It diminishes the frequency of the pulsations, increases their vigour, and calms dyspnœa. It is an efficient sedative of the nervous system, and has a favourable effect on insomnia. The wet pack acts thus very rapidly on the fever and procures sleep.

GERMANY.

Berlin, Dec. 6th, 1913.

At the Gesellschaft für Chirurgie Hr. Karewski discussed the

Clinical Course and Diagnosis of Retroperitoneal Lipoma.

In the case related he said there were all possible kinds of adhesions. The sole characteristic sign was the retroperitoneal situation. 110 cases had been collected and described by Lobstein, from which the following train of symptoms had been observed. The majority of the cases were in women, as it was in them that the greatest tendency to the affection was met with. These tumours were frequently mistaken for ovarion cysts. The affection ran its course either without symptoms or with symptoms of a nervous kind. There was a considerable growth which led to crowding, often with local disturbances. Colic was rare, as also was interference with the lumen of the bowel. The course was long. The strength gave way only slowly. Taken as a whole the symptoms were not at all clear.

The patient was a woman, æt. 40, who had had two natural labours and one tubal pregnancy that had recovered spontaneously. Six years ago she had colicky pains in the upper part of the abdomen which seemed to indicate something wrong with stomach, the gall bladder, or the intestines. Later on vomiting took place without any colic. The liver was below its normal level. Further attacks of severe pain led to desire for an operation, but the speaker at the time declined to operate. Some months ago the pains were renewed with violence. During a period of observation of eight weeks there were observed: hyperacidity, normal urine, flatulence, depression of the liver and of the right kidney, enteroptosis especially of the transverse colon. During a journey at the new year she had the feeling of a rent in the right upper part of the abdomen, and after this she lost weight up to 10 lbs. The abdomen was distended, and the liver enlarged, no ascites, no œdema, Wassermann test negative. The diagnosis now lay between: hydrops of the gall bladder, syphilis affecting the liver, echinococcus, and finally a retroperitoneal tumour. Röntgen examination showed, stomach and small intestines pushed to the left, disappearance of the enteroptosis, no fluid passed into the small intestine through the ileocæcal valve. Per vaginam the tumour could be felt along with the uterus.

An exploratory operation showed a retroperitoneal fibrolipoma attached to the colon and the vena cava. The wound was now completely drained. Four weeks later an abscess opened, which appeared to come from an opening in the ascending colon. The patient's troubles were over for the present, and she had gained 13 lbs. in weight. The tumour, which did not show any malignant tendency, sprang from the fatty capsule at the upper pole of the right kidney.

Hr. Biernath related a case of

Bullet Wound of Lung and Kidney.

The patient was a young woman, æt. 22, who shot herself with a Browning revolver with suicidal intent. Two hours later she was admitted into hospital. There was no external bleeding. The entrance wound was in the third intercostal space three finger-breadths from the left margin of the sternum; no exit wound was visible. The next day the urine was bloody and there were appearances of peritoneal irritation. Cystoscopy, on the fourth day, showed that the blood in the urine came from the right kidney. A Röntgen photo taken with the ureter catheter in position showed a bullet in the lower pole of the kidney. On the 10th day the urine was purulent, and on the 16th there was a rigor. On the 17th day the kidney along with the missile was removed by Prof. Riese. The patient was discharged during the 7th week. At the middle of the kidney was a small opening, the size of a pfennig, which led into injured tissue about the hilus of the kidney. In the centre of the kidney was an infarct the size of a walnut. The different veins contained a yellow-coloured thrombus, in which cocci were included.

At the Verein f. Innere Medizin und Kinderheilkunde, Hr. Oberwarth related a case of

Spasm of the Pylorus in an Infant.

The child was but eight weeks old. Peristaltic movements were present, but the food stagnated in the stomach; also the child was losing flesh. The speaker said he had seen on the whole twenty similar cases, and he had seen a more favourable termination to the affection than had generally been ascribed to it. The treatment consisted in giving only the smallest quantity of human milk out of a bottle at one time, and in the intervals enemata of milk and saline. He did not wash out the stomach except in cases in which food stagnated in it or when the appetite had quite been lost.

AUSTRIA.

Vienna, Dec. 6th, 1913.

The discussion of Dr. Falta's communication on the

Theory and Treatment of Diabetes Mellitus

was resumed at the recent meeting of K.k. Gesellschaft der Aerzte. Dr. O. Kolischer recalled the publication of a theory of diabetes by himself fifteen years ago, of which the following were the principal features:—The normal continuous process of the splitting off of sugar from the protoplasm of the tissues, and from highly complex molecular systems, appears to be intensified in diabetes, either by nervous influence or from the presence of some toxic element. Accordingly, it is in this regard that we must speak of an over-production of sugar in the system. The amount of nitrogen excreted in the urine is, however, by no means a reliable measure of the sugar derived from albuminous sources, as retention of the nitrogenous residue may take place, which, in a diabetic organism, must be sooner reduced to carbon than to nitrogen. This splitting off of sugar in the organism takes place in the stimulation of every cell, and especially during that of the process of nutrition. But as we know that albumin is the aliment which furnishes the most powerful nutritive stimulus, so is it also of all nutritive materials introduced into the diabetic system that which elicits the most copious separation of sugar. The results which had obtained in clinical experiments on diabetic cases, by diminishing the supply of albumin, quite harmonised with this view. The experience of many years, too, of the effects of a vegetable diet went to show that there was a considerable difference in the proportional separation of sugar in the respective cases of animal and vegetable albumin. On this account he had already warmly advocated the use of a vegetable diet in diabetes. Another influence of great effect in the treatment of diabetes was furnished by our knowledge of the effects of a general lowering of the nutritive process. In concluding, Dr. Kolischer pointed to the analogy between his own system of diabetic therapeusis and that of the new era now ushered in by Dr. Falta. Its features could be arranged under four headings—(1) The individualising treatment had, as before, to be determined by the proportional degree of tolerance of each diabetic patient for carbohydrates, and, still more especially, by the nutritional necessities of the organism, especially as regards the minimum of nutriment with which the patient could be maintained. The nutritional demand should be gradually lowered as far as possible. (2) As the degree of tolerance for carbohydrates largely depends on the composition of the additional diet given with them, aliments should always be chosen in which the maximum proportion is of quality compatible with carbohydrate foods. With this prescription is included the device of furnishing the very smallest necessary quantity of albuminous material. (3) A vegetable diet, with the necessary selection, is specially suitable to diabetics, as it contrasts with every other form of alimentation by offering the maximum proportion of carbohydrates with the minimum of albumin and the minimum of calories. (4) The administration of fatty foods should be regulated solely by the nutritional demand in each case.

Dr. O. Porges pointed out that the question of the ætiology of diabetes had not yet been solved. While, according to one view, diabetes was merely an exaggeration of the normal process of sugar production in the organism, in the absence of the sufficient influence which normally controls the physiological formation of sugar, the other conception of diabetes is that of a deranged sugar oxidation, on account of which sugar accumulates in the blood, but which cannot, as in the normal condition, lead to deposition of glycogen, as "the sugar-hungry hepatic cells are continually sending out signals for the new formation of sugar." This theory also necessitates the assumption that the cells which are already swimming in sugar at the same time determine the continuous formation and conveyance thereunto of fresh quantities of sugar. What then does experimental research on metabolism prove in connection with either of these theories? While gastric or intravenous introduction or sugar determines an increase of the respiratory quotient in the normal individual, this is not the case with the diabetic. The normal individual converts the sugar to good account, as Dr. Falta expressed it: the diabetic did not. Now, in what does each conversion consist? Is the process most nearly one of combustion? The increase of the respiratory quotient speaks in favour of this view. So is the conception of Dr. Porges, who believes that the "conversion" consists in the deposition as glycogen in the liver. This view is corroborated by the fact that, in glycogen-free animals the hepatic glycogen is demonstrably replaced on the introduction of sugar, even when this is by intravenous injection. Accumulation of hepatic glycogen also results from oxidation of albumin and fat in the liver—hence an increase of the respiratory quotient. In diabetes there was no formation of glycogen in the liver after the ingestion of sugar, as many researches go to prove; inasmuch as, if the oxidation of albumin and fat in the liver is not stayed the respiratory quotient remains unaltered. This view also receives powerful support from numerous researches carried out recently in the Emden laboratory at Frankfort. Emden has shown, in company with a number of fellow-workers, that the still vital, bloodless liver oxidises fatty and formic acids, with formation of characteristic intermediate products—acetone bodies, among others. It is interesting to note that only the glycogen-free liver, or one poor in glycogen, effects this oxidation, not a liver rich in glycogen. It was also decisively proved by test-tube research in the laboratory that the supply of albumin and fat regulates the amount of the hepatic glycogen. Muscular tissue deprived of blood by the same *technique* showed no recognisable derivatives of the oxidation of derivatives of albumin or fat.

Dr. Porges then went on to point out that theories have recently been advocated with an object of reconciling the opposed views. It has, indeed, been admitted that the production of glycogen was diminished in diabetes, and this deficiency has been made responsible for the defective combustion of sugar. It has been said that the sugar-consuming organs (muscles) must first have the sugar deposited as glycogen before they can consume it; then, as the deposition of glycogen in the muscles is impaired, the sugar is not consumed. This view is not, however, sustainable in the presence of many well-attested clinical facts. Then, again, the formation of muscle glycogen is not impaired in diabetes; on the contrary, it is often found—as was first shown by research work in the Starling Institute—that the glycogen of the cardiac muscle is increased, while there is also a deposition of glycogen in organs previously glycogen-free. Diabetes is thus a result of defective glycogenesis in the liver, which in the altered conditions forms the sugar directly from albumin and fat. With regard to the practical therapeusis, oatmeal and flour were relatively easily "converted" in the normal way, and he thought that this fact threw some light on the much-discussed problems of diabetes. Meal and flour foods were, according to many authorities, normally converted by diabetics only in such preparations as porridge, custard, etc.; not in form of bread. But in these forms of cooking there are large proportions of fatty matter added to the carbohydrates, and this suggests the possibility that simultaneous provision of fat makes that of the carbohydrate more easy. He thought that as the fat was longer retained in the stomach, inundation of the intestine with starch, which was so readily converted into sugar, was thereby retarded.

UNITED STATES OF AMERICA.

New York, Dec. 1st, 1913.

THE CLINICAL CONGRESS OF SURGEONS.

The fourth annual meeting of the Clinical Congress of Surgeons of North America was held in Orchestra Hall, Chicago, from Monday, November 10th to Saturday, November 15th, under the presidency of Dr. George Emerson Brewer, of New York. As the name implies these meetings are pre-eminently clinical and, from this standpoint, the meeting just over in Chicago compared favourably with that of the previous year in New York. Both Chicago and New York contain a vast wealth of material, for than these two cities there are no other centres of population that have within their bounds a more cosmopolitan population. In fact, there are no cities which have so large a number of people drawn from all quarters of the globe. In addition to this wealth of material, the hospitals and institutions for the sick are plentiful and extremely well equipped in these cities. Last year New York easily surpassed anything ever before attempted from the clinical standpoint, and while comparisons would be invidious, it may be said that Chicago well upheld her great reputation at a surgical centre and that the clinics and the meetings at which papers were read passed off without a hitch.

Among the British guests were Sir Rickman Godlee, President of the Royal College of Surgeons of England, who came over to take part in the convocation exercises of the newly-founded American College of Surgeons and to read a message from the Council of the London Royal College. In this message felicitations were tendered to the American medical profession, and the hope expressed that the College would grow and prosper, and that by its influence the ideals and standards of surgery in America would be advanced and maintained on a high plane. There were also present Sir William Arbuthnot Lane and Mr. Herbert J. Paterson, of London. The meeting was well attended, there being in the neighbourhood of 4,000 members at the opening session.

Dr. E. W. Andrews, Chairman of the Committee of Arrangements, welcomed the members, and then introduced Sir Rickman Godlee, who said that he had been impressed with the enormous amount of clinical material which he had seen at all the hospitals he had visited and had been greatly struck with the methodical way in which instruction was carried on at these institutions. After congratulatory remarks by Dr. Murray McLaren, president of the Canadian Medical Association, and by Professor Krönig and Dr. C. J. Gauss, of Frieburg, Dr. George E. Emerson delivered the presidential address, this being a preliminary report on a

Simple and Rapid Method of Pyloric Closure in Gastro-enterostomy.

Dr. Brewer reviewed the various methods which had been suggested in the past, and emphasised the fact that the present desideratum was for a method which could be as quickly and simply executed as a simple ligature, and at the same time be as permanent in its results as the prolonged operation of Von Eiselberg. Dr. Brewer said that his method consisted in constriction of the pylorus by an aluminium band, which was easily passed round the tube at the point, and quickly rolled with the fingers into an unyielding ring with sufficient compression to obliterate the lumen of the tube, but not to compromise the vitality of the compressed tissues. Experiments upon dogs had shown that this method of closure produced a complete occlusion of the pylorus, as proved by the fact that water would not pass the constricted point where the stomach was distended, and also by the fact that sections through the pylorus and aluminium ring showed by gross and microscopic examination, not only that the pylorus was closed, but that the vitality of the tissues was not impaired. Another series of experiments showed that the same method could be applied to the pyloric antrum, and also that the pylorus which had been closed for some months could have its function again restored by a second laparotomy and removal of the aluminum band. While Dr. Brewer had not employed this method on the human subject the animal experiments had been so conclusive, that he believed it to be the the simplest and safest method yet proposed for these cases.

On Tuesday, Nov. 11th, Dr. John B. Deaver, of Philadelphia, read a paper on

Gastric Hœmorrhage,

in which he said that such hæmorrhage due to malignant disease of the stomach was not commonly profuse and sudden. The hæmorrhage from malignant ulceration, as a rule, was a slow seepage which gave rise to little systemic effect of bleeding, but revealed itself by the process of coffee-ground vomitus or melæna. Sudden hæmorrhage was one of the modes of termination of gastric carcinoma, but in all but the rarest instances such an event was but the termination of an ulcerated myoma of the stomach. Operation might be indicated in gastric carcinoma when hæmorrhage chanced to be an early symptom and there was still hope of cure ; or it might be indicated in advanced or otherwise inoperable cancer when hæmorrhage was so profuse and persistent as to shorten even the period of prognosis given to cancer. In this case the measures to be adopted were excision, gastro-enterostomy or jejunostomy, in accordance with the pathology found at operation. But four most essential points remained to be settled : (1) The recognition of suitable cases ; (2) the time to operate ; (3) the type of operation to be performed ; (4) the proof of our position by mortality statistics.

Dr. A. J. Oschner, of Chicago, said that gastric hæmorrhage must not be regarded primarily as a surgical emergency. An idea which had permeated the surgical conscience as a result of the surgical possibilities of the past few decades had given rise to the feeling that when any very serious condition occurred it must be attacked surgically. This was true only when the good judgment of the surgeon indicated that the patient was in such a condition that surgical treatment would give the greatest possibility of cure. A careful and accurate diagnosis was the foundation for this judgment based upon a thorough knowedge of the history of such cases. The actual deathrate from chronic hæmorrhages of the stomach was undoubtedly large, and must be considered from the standpoint of ulcer of the stomach, and that treatment must again be based upon a diagnosis which now could be made with a great degree of certainty.

Mr. Herbert J. Paterson, of London, dealt with the operation of

Gastro-jejunostomy,

and the principles which should determine its use. He said, in part, that for a good many years he had been advocating the view that gastro-jejunostomy was a physiological one. Sir Berkeley Moynihan had expressed his belief that the "physiological explanation of gastro-jejunostomy is rot."

Mr. Paterson gave the reasons for his belief at considerable length, the main reason being that after a gastro-jejunostomy there was a constant increase of the mineral chlorides of the gastric juice. The increase must be due to chlorides added to the gastric juice by the entrance of bile and pancreatic juice, because (1) the total chlorides of the gastric contents were diminished ; (2) undoing gastro-jejunostomy diminished once more the amount of mineral chlorides ; (3) if an entero-anastomosis be performed the increase of the mineral chlorides did not occur ; (4) in cases in which there was a marked excess of mineral chlorides ; (5) as a rule, the increase of mineral chlorides did not follow operations other than gastro-jejunostomy. Doubtless part of this increase was due to the neutralisation of free hydrochloric acid, and the consequent formation of sodium chloride. This did not affect the argument, because (1) the neutralisation must be caused by the carbonates of the bile and pancreatic juice ; (2) if before gastro-jejunostomy, free hydrochloric acid be absent from the gastric contents, there was still an increase of the mineral chlorides after gastro-jejunostomy. The four practical lessons to be learned were : (1) that the type of gastro-jejunostomy employed is of less importance than the manner in which it is performed ; (2) that if gastro-jejunostomy be a physiological operation its use for the treatment of gastric hæmorrhage is correct and explicable ; (3) that occlusion of the pylorus is an unnecessary complication of gastro-jejunostomy and is based on erroneous pathology ; (4) that if gastro-jejunostomy be a physiological operation then it is as efficient a treatment for ulcers of the body of the stomach as for ulcers near the pylorus ; in other words, gastro-jejunostomy is preferable to excision.

Dr. Carl Beck, of Chicago, in discussing Mr. Paterson's paper, remarked that as to whether pyloric exclusion was practically useless, further experimentation in the workshops of surgeons would determine. At present surgeons could only take the say-so of Mr. Paterson for it.

(*To be continued*).

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH.

Indian Students in Edinburgh.

The announcement by the India Office that an inquiry is to be held by a sub-committee of the London Advisory Committee into alleged grievances of Indian students has been received with some interest in Edinburgh, on account of the number of Indians who now attend the university. It is estimated that there are between 1,600 and 1,700 Indians studying in the United Kingdom, of whom more than 700 are members of the Inns of Court, while more than 300 are in Edinburgh and Glasgow. The sole object of the Indian student department is to help students to obtain the facilities they require, and to obviate difficulties they may meet. Most of the students do credit to their training here, but as their numbers increase the competition for appointment and opportunities for training increases also, and so, it is to be feared, does prejudice increase as well. The department exercises a certain amount of financial guardianship over some students, and has appointed local advisers in different centres. Dr. James Miller is the local adviser in Edinburgh. In the report of the department, the question of race prejudice is touched upon, and it is remarked that signs of this prejudice have been shown by certain Edinburgh students, chiefly those who, like the Indians, are British subjects and visitors from overseas. Prejudice of this kind, says the report, so far as it is conscious and deliberate, is happily not widespread. It is found in only a few young men who do not understand what the British Empire stands for, or what the obligation of good manners means. There is, unfortunately, no doubt that what the report states is correct. At present there can be no question that a certain amount of scarcely veiled prejudice against native students exists in Edinburgh. There are two main reasons for this state of things: first, the increase in the numbers of the Indian students, and, secondly, the greater prevalence of colonial opinion in the University. Twenty or more years ago, when Indian students were much less numerous, they were received by their fellows on a much more equal footing, and the change that has taken place is regretted by many who have witnessed it. There is, however, no use blinking the fact that we have in the University the colour problem, though on a small scale. It is as useless to urge that the traditions, mode of life, and religion of the East do not form a bar to intimate social intercourse with the West as it is to urge that the colonial prejudice against the coloured races is unjust and unfounded. Both these facts exist. Intimate relationship is as matters stand impossible, and racial prejudices strong. But surely courtesy demands that these differences shall be minimised, not exaggerated, and that in undergraduate university life tolerance be extended all round. Those who are most interested in Indian affairs cannot but regret the impression of England which many of our fellow subjects take home with them. We would gladly see the day come when the necessity for educating Indians in this country becomes less. The only permanent means of avoiding friction of a very undesirable kind would be, it seems to us, to foster higher university education in India, so that, unless in exceptional cases, the Indian student need not come to one of our own universities.

National Medical Union.

This new association has received a number of recruits from Edinburgh. The Medical Guild, which consists of non-panel practitioners, has become one of the Federated Societies, and Professor Russell, Edinburgh, has been elected one of the Presidents of the National Medical Union. Opinion is divided among the members of the Guild as to the advisability of remaining attached to the British Medical Association, or resigning, and a considerable number of men who are not on the panel have resigned already. The decision of the Association to raise the subscription to two guineas will in all probability act as the proverbial last straw, and decide a good many waverers or merely indifferent members to withdraw. After all, to a great many doctors the chief advantage of belonging to the Association has been the *Journal*, and no doubt many will feel indisposed to pay a larger subscription for what seem to them very doubtful benefits when they can obtain the *Journal*, or one of the other weeklies, at the old rate through the ordinary channels of distribution.

Insured Persons in the Royal Infirmary, Edinburgh.

A conference between the managers of the Infirmary and delegates from local approved societies and Insurance Committees was held in the Infirmary on December 5th, at which the managers pointed out their attitude towards insured persons, explaining that in only a small number of cases, such as was clearly within the competence of panel doctors, had insured persons been referred to their own doctors after applying to the Infirmary. They also pointed out that during the half-year to July 14th, 1913, 2,540 insured persons had been admitted and treated, at a cost of £10,946, and on that score they claimed decided and substantial financial support from approved societies. The appeal was not made in the form of diminishing subscriptions, but on grounds of justice. After some discussion, for the most part favourable, a resolution was agreed to to the effect that while the societies were not committed in any way the representatives agreed to recommend all the societies to take the needs of this hospital into favourable consideration.

Highlands and Islands Medical Service Board.

The King has been pleased to appoint Norman Purvis Walker, M.D., Treasurer of the Royal College of Physicians, Edinburgh, to be an additional member of the Highlands and Islands (Medical Service) Board.

GLASGOW.

The Victoria Infirmary, Glasgow.

The annual report of this Institution has just been published. Like that of the Western Infirmary, it shows a large deficit in the ordinary income as compared with the expenditure, but in this case again, the extraordinary income, consisting of legacies, donations, etc., makes up for the deficiency in the ordinary income, and it also allows the governors to add to capital the handsome sum of £9,429 16s. 4d. The daily average number of patients in the Infirmary during the year was 253. At the Infirmary dispensary for outdoor patients, 3,380 individual cases were dealt with, involving 11,294 consultations. The corresponding numbers for the previous year were 4,591 and 15,262. This reduction in the number of cases treated at the dispensary has been caused, it is stated, by the National Health Insurance Act, whereby patients are now treated by their panel doctors. As in the case of the Western Infirmary, the employees' subscriptions show an increase, notwithstanding the Insurance Act. Of the cases treated to a conclusion in the wards, 317 or a percentage of 9.02 died. Deducting, however, 78 cases which were of such a serious nature that the patients died within 48 hours after admission, the death-rate is reduced to 7.00. There were no vacant beds at any time during the year, and generally there were from 160 to 200 patients waiting for admission.

The Risks of General Practice.

The risks to which the profession is exposed are again exemplified in an action which has been raised in the Court of Session. A lady sues a Lanarkshire practitioner for £500 as damages. She states that on June 5th, while pruning in her garden, she cut the little finger of her left hand very deeply. She washed and dressed the wound, but as it was very painful next day she sent for the defender, who diagnosed that the finger was poisoned through some garden matter having got into the wound. The pain and swelling, she says, increased in spite of the defender's treatment, and on June 23rd she went to Glasgow and consulted another doctor, who amputated the finger. The pursuer complains that the loss of the finger was occasioned by the defender's treatment of it. The defender denies that he was guilty of fault or negligence, and he states that he was most careful in his attention to the pursuer's wound and exhibited no lack of skill in his treatment. The defender is a practitioner of 21 years' standing.

Maternity Benefit.

An interesting lecture was delivered on the 3rd inst. on this subject at a meeting in the Council Room of the Charity Organisation Society, by Dr. Sutherland, who is Assistant Medical Officer of Health. She stated that since maternity benefit came into operation, a marked difference had resulted in the manner in which notification of births was made. This was shown by a decrease of notifications through the Maternity Hospital and by an increase in notifications by general practitioners in private practice and by midwives. Inquiry by the Public Health Authority which had been made into 2,552 cases of births notified, showed that the insurance benefit was received in 2,145 of these; in 214 cases it was found impossible to obtain information; in 56 cases one of the parents was insured, although no benefit was received; while in 137 cases neither parent was insured.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

LONDON HOSPITAL APPOINTMENTS.

To the Editor of The Medical Press and Circular.

Sir,—While I have no desire to question the opinion expressed in your leading article of the 3rd inst. to the effect that "it would be of the greatest possible ultimate value to the public, as well as to the cause of medical science and to the patients, were an adequate salary to be attached to all hospital posts," exception must be taken, I am afraid, to certain of your arguments.

You write that "the philanthropists who administer the affairs of the charity are rewarded by social prominence and in some instances by titular distinction," and that "it may be said generally of hospitals that everyone is paid directly or indirectly for services rendered, except the members of the honorary staff upon whom falls the heat and burden of the day."

Such reasoning is to my mind, however, absolutely futile, for is it not a fact that your previous remark is likewise true in the case of consultants, medical and surgical, who moreover owe the practice they enjoy to the professional reputation they acquire in the hospitals at which they hold or have held appointments?

Could you point to unattached consultants who, notwithstanding, have acquired practices equally large, and who by virtue of their professional pre-eminence have attained to titular distinction, it might be a different matter.

I am, Sir, yours truly,
Justitia.

London, December 5th, 1913.

REDISCOVERY OF A SYPHILIS SPECIFIC.

To the Editor of The Medical Press and Circular.

Sir,—We are now told that "Antileutin," the new remedy for syphilis, may dethrone salvarsan (an arsenical compound). We are also told by Tsuzuki that the best results are obtained when it is combined with iodides and mercury.

What is antileutin, anyhow? A simple compound of antimony oxide. But for years our forefathers treated syphilis with Plummer's pill—antimony, calomel, and guaiacum, whilst cases resistent to this process were treated with Donovan's solution—arsenic, iodides, and mercury.

I think Wallace, of Dublin, when surgeon to Jarvis Street Hospital, advocated this line of therapeusis.

I am, Sir, yours truly,
J. C. McWalter.

Dublin, December 4th, 1913

THE ALCOHOL QUESTION.

To the Editor of The Medical Press and Circular.

Sir,—In a few pithy and wise sentences, Dr. Robert Lee in a recent letter to your paper indicates the real crux of the alcohol question. Alcohol is a poison; so are tobacco, tea, and cayenne pepper; so also are mutton chops and muffins—when taken to excess. Many of our most useful drugs are deadly poisons—as, for example, arsenic, strychnine, belladonna. Alcohol is a poison; but consumed in small doses and under certain conditions it passes through the system without giving rise to any injury recognisable to minute scientific examination. On the contrary, its stimulating effects render it in suitable cases an extremely valuable therapeutical agent. It is unfortunate that this fundamental fact is not acknowledged and acted upon by all those who devote themselves to what is called "temperance" work. An immense amount of harm is still being done by fanatical propaganda in this direction. Fanatics often talk as though all consumers of alcohol are inebriates, in the habit of constantly imbibing doses of crude spirit for the pleasure of the more or less complete intoxication thus produced. They ignore the difference between raw spirits and wholesome beer or fine light matured wine free from excess of added alcohol. In spite of some setting back, in which at present, and it is to be hoped only temporarily, the alcoholic quack medicines now so widely advertised are very active, we are evolving a more temperate society. Among all and every class drunkenness is nowadays looked upon with more or less disgust and loathing. A hundred years ago most gentlemen habitually got drunk at the dinner table. Herbert Spencer somewhere points out that a savage tribe when it gave up torturing, killing, cooking and eating its prisoners of war, and kept them only as slaves, displayed a real advance in civilisation. If all our people can be gradually brought to the position of our at present most refined classes, if they can be brought to appreciate what is elegant instead of what is coarse in alcoholic beverages, to prefer a clean, fine flavoured beer of the lager type to the loaded liquor which a brutal palate demands, we shall have perhaps attained as near to the millenium in this connection as mankind in its present inferior stage of ethical development is capable of reaching.

I am, Sir, yours truly,
Medical Temperance Reformer.

December 6th, 1913.

OBITUARY.

DEPUTY INSPECTOR-GENERAL T. J. PRESTON, R.N.

We regret to announce the death of Mr. Theodore Julian Preston, Deputy Inspector-General of the Royal Navy, which has taken place at his residence, 16, St. John's Park, Blackheath, aged 66. The deceased, who was the son of the late Dr. W. J. Preston, received his medical training at St. Mary's Hospital, and after qualifying as M.R.C.S. in 1870 and L.R.C.P. in 1872, he held surgical appointments at Brighton and Hove Lying-in Hospital and East Grinstead General Dispensary. He entered the Navy as a surgeon in 1873, and was promoted to the rank of staff surgeon in 1885, and to that of fleet surgeon in 1894. He was surgeon of H.M.S. *Sultan* at the bombardment of Alexandria in 1882, and during the Egyptian War. After the former action he landed in medical charge of the Royal

Marines, and was also employed on shore as senior medical officer of the Royal Marine Battalion. He became attached to Sir Evelyn Wood's Brigade for the defence of Alexandria and was present at the capitulation and surrender of the Aboukir and Rosetta Forts, and received the Egyptian medal, the Alexandria Clasp, and the Khedive's Bronze Star In 1888 he was awarded the Sir Gilbert Blane Gold Medal for "skill, diligence, humanity, and learning in the exercise of his professional duties" in the Navy. He retired from the Navy Medical Service in 1902 with the honorary rank of Deputy Inspector-General of Hospitals and Fleets.

SPECIAL REPORTS.

THE RESEARCH DEFENCE SOCIETY (NOTTINGHAM BRANCH).

THE annual meeting of the above society was held at the Medical Club, Nottingham, on December 1st, 1913.

The following address was delivered by Bishop Frodsham, who occupied the chair:—

The triumphs of medical research have had such general and far-reaching effects in England that it is difficult for the majority of people to realise what England would be without them. Medical men are able to assess what medical science has wrought in little more than a generation. Ordinary people like myself find it requires an effort of imagination to realise the changed state of affairs. In one respect I have an advantage over many in England. For ten or twelve years I have wandered to and fro in a huge tropical land where medical research was practically unknown. I was brought face to face with diseases, some new and others old, all of which were imperfectly understood. Do not go away with the idea that tropical Australia is a peculiarly unhealthy place. It is nothing of the sort. There are certain facts connected with the atmosphere, and with the huge sea areas of the Southern Hemisphere, which make even the tropical parts of Australia phenomenally healthy. But as in all tropics, there are diseases peculiar to those parts against which white people have not become, as they have in their own milieu, partially immune.

There are certain diseases in tropical Australia, the names of which are unfamiliar, perhaps meaningless, to the vast majority of English people. Epidemic dysentery, dengué fever, ankylostomiasis, beri-beri, sprue, filariasis. Some of these diseases are well known to science, and their remedies have been found through scientific research in the Empire, in Manila, and in Japan. Others are still very obscure. Others again are easily diagnosed, but the remedy has not yet been found. Take, for instance, filariasis. It affects animals as well as men, and in some districts to the extent of perhaps 10 per cent. of the population. But although the disease is so easily recognised, in both cause and effect, its remedy, I believe I am right in saying, is still unknown. This is a case where the need for greater scientific knowledge becomes imperative. Very late one night, when the steamer I happened to be travelling upon was unloading at a certain tropical port, a man came to my cabin, and woke me up to tell me that he was suffering from such a horrible form of filariasis that he thought he dare not continue to live. The unspeakable misery on the man's face, as he sat by my side, and we talked of the possibility of a remedy being found, set me very steadfastly on a task I was at the time feeling excessively irksome, the formation of the institute for the study of tropical diseases in Australia. That institute has been founded at last, and I regard my own modest effort in its foundation as one of the best things I have done in my life. It is already helping, and will help yet more, to lay the horrible spectre of unknown diseases from the lives of English men and women who are building a home for the white race in that part of the Empire.

I have told you all this because I want to make it quite plain that in assisting in the formation of this institute for the study of tropical diseases I knew, as all Australians knew, that it would entail to a certain extent experiments upon living animals. The experiments, as everywhere else, would be principally by inoculation—but still they would be experiments. Their result will be found in the future. But consider the triumphs of past research by which you are safeguarded at present. The method was the same. The knowledge of antiseptics, anæsthetics, of antitoxins, of all the thousand and one remedies that have relieved human and animal suffering, has been gained by experiments upon animals. At certain stages of research the scientists have paid the price of knowledge in their own lives. This was the case of those brave American medical students who submitted to voluntary inoculation of yellow fever to discover how long the Stegomyia mosquito could be the host of the disease. It would be unthinkable that any could doubt the heroism, the sincerity of such men. But the same spirit is in the hearts and lives of others who are often bespattered with contumely and lifted up to abuse. I ask you to believe that it is not an incredible thing that medical scientists have been moved throughout by a sincere desire to make the aching hours of pain less long, or less hopeless, to suffering men and women whom they may never know. I ask you to believe of some at least that they have done so as an act of service to One who said of the sick "Inasmuch as ye did it unto one of the least of these my brethren ye did it unto Me."

The Research Defence Society is not a society of scientific experimenters. I stand halfway between the few scientific men who conduct the experiments and the many who simply want to see fair play. Am I right in saying for you that much as we value research, and believe it to be morally justifiable, we do not oppose restrictions and regulations which aim, not at hampering all research, but at reducing the danger of any animal suffering unnecessarily? We are opposed to allowing judgment to go by default against those whom it is the fashion in certain quarters to dub "vivisectors." We are anxious to publish the whole truth, and we believe that truth is great and will in the end prevail. No member of this society would denounce all opponents of experiments on animals even though he might regard them as often "grievously misinformed and overweighted by sentiment." But the whole temper of British people is at the bottom opposed to fanaticism and prejudice, and it is against the fanatic and the prejudiced man that this society is in arms. Like Cardinal Newman, I am inclined to think that prejudice corrupts the soul "beyond those sins which are called deadly." It is associated with such an astonishing want of mere natural charity. It possesses such an unaccountable readiness to believe evil of others. And from prejudice, fanaticism, and all uncharitableness Good Lord deliver us.

ROYAL COMMISSION ON VENEREAL DISEASES.

ON the 1st instant, Dr. Burnett Ham, who from 1909 until this year was head of the Health Department in the State of Victoria, described the measures which have recently been taken in connection with venereal diseases in that State. In 1908 the Australian Medical Congress passed the following resolution: "That syphilis is responsible for an enormous amount of damage to mankind, and that preventive and remedial measures directed against it are worthy of the utmost consideration." Later a deputation waited upon the Premier of Victoria in 1909 to urge the consideration of this matter, and Dr. Ham was directed to draw up a scheme for its investigation, and an advisory committee consisting of leading medical men and women in Melbourne was appointed to act with him.

As a first step to ascertain the facts as precisely as possible it was decided to make syphilis a compulsorily notifiable disease in the Melbourne Metropolitan area. In actual practice the compulsory nature of the notification was not insisted upon as no penalties for failure to notify were enforced, but it was felt that unless an official flavour was given to the requirement to notify the response from the medical practitioners would be but small. There was at first some opposition on the part of the medical profession to the proposed notification, but this was to some extent removed when it was made clear that the notification was to be impersonal, that no names were to be given, and that consequently no administrative action could be taken on the notification so far as the patient was concerned.

As a matter of fact, during the year in which the notification order was in force only 110 out of the 350 to 400 practitioners in the metropolitan area actually notified cases. Thus the measure adopted was not compulsory notification as ordinarily understood, but rather an experiment made with a view to ascertaining the amount of syphilis in the city. In connection with the notification arrangements a circular was issued to medical practitioners explaining the kind of cases they were expected to notify, and the doctors were also asked to supply with each notification a sample of the patient's blood for the purpose of testing by the Wassermann reaction.

In the course of a year, 5,500 notifications were made and an equal number of samples of blood submitted; 3,500 of these notifications were made by private practitioners, 900 by the Melbourne Hospital, and 1,100 by the Eye and Ear Hospital. Of the 5,500 Wassermann tests for syphilis which were carried out 1,900 gave positive and 400 partial reactions, and it was calculated that this corresponded to a number of syphilitic cases equivalent to 0.5 per cent. of the population of the area. This figure was very much lower than had been anticipated.

An investigation was also carried on at the eye and ear clinics of Dr. Barrett. All patients presenting themselves during a certain period, irrespective of the disease from which they were suffering, were tested by the Wassermann reaction. The results showed that out of 550 cases 75, or 13.6 per cent., gave positive or partial reactions. With regard to gonorrhœa, a statement was furnished to the Advisory Committee by the Women's Hospital, from which it appeared that in the view of the staff at least 50 per cent. of the major operations performed at the Hospital were due to gonorrhœa.

The Advisory Committee, after submitting their report to the Government, endeavoured to induce the Press to take up the question, and in this they met with a certain amount of success. The National Council of Women were also approached, and they agreed to assist in an educational campaign and to co-operate with any reasonable measures the Government might bring in, provided that there was no legislation on the lines of the Contagious Diseases Acts and that no difference was made as between men and women. The Advisory Committee did not recommend legislation, but they advised the Government to subsidise the provision of wards for the reception of venereal cases in the general hospitals. This recommendation was adopted by the Government and free beds were provided, 24 for males at the Alfred Hospital, and 20 for females at the Women's Hospital. The wards were equipped by the Government with the most modern appliances, and in addition a subsidy was made to the Melbourne University to provide for the carrying out of Wassermann tests.

At first there was some difficulty in filling the beds provided, but as it became known that the treatment was in a general ward, and that the patients would not be dealt with differently from those in the other wards, a good demand for beds arose. The establishment of a night clinic at the Alfred Hospital also helped to popularise the arrangements.

Dr. Ham thought that the experiments conducted at Melbourne had led to a greater interest in the subject, and that in securing early treatment and early diagnosis they had achieved an important result. A Health Bill was at the present time before the Victorian Legislature which contained provisions for adequate and gratuitous treatment of patients, for the prohibition of treatment by unqualified persons, and for making the transmission knowingly of venereal disease a penal offence.

REVIEWS OF BOOKS.

THE NERVOUS AND CHEMICAL REGULATORS OF METABOLISM. (*a*)

We have read these lectures with great pleasure and interest. They give a remarkably concise and satisfactory account of present knowledge regarding the functions of the ductless glands, and the author has done good service in arranging this knowledge in excellent perspective. He shows us that three factors are concerned in the co-ordination of the body. These are (1) hereditary inertia or inherited developmental tendencies, (2) the nervous system, and (3) the internal secretions.

The first factor is dominant in embryonic life, the two latter become more prominent as development advances. There are many striking ideas and suggestions throughout the book. We are told that administration of adrenalin by the mouth has no effect, and that subcutaneous injection *is said* to raise the pressure in man. We have little doubt that subcutaneous injection of adrenalin does raise the pressure in man, and it would surely be an easy matter for the author to investigate the point for himself. A note of caution is sounded regarding the effect of secretion on the pancreas, and it is suggested that the nerve control may yet be shown to have a greater importance than is attached to it at present. The condition of the thymus in *mors thymica* is thought to have nothing to do with the fatal issue, and the term may be considered a misnomer.

The symptoms of Addison's disease are attributed to disease of the cortical portion of the suprarenal gland, "for there is no evidence that adrenalin exercises any tonic effect on skeletal muscle."

We could have wished that the author had expended a little care on the presentment of his work—it is abundantly worthy of the best possible setting. Unfortunately little attention appears to have been paid to the matter. The book is throughout too condensed, and too much technical knowledge on the part of the reader is assumed. The author takes such terms as *metamere* and *petromyzon* in his stride, and is niggardly in the matter of explanations of any kind. The latter half of page 11 is downright bad English. The third paragraph on page 39 is ambiguous, and we are solemnly informed on page 159 that "*birds* . . . undergo a constant transition from the state of the apathetic eunuch to that of energetic *manhood*." We might add that the figures are marked with letters which in many cases are not referred to either in the legend or in the text.

For the intrinsic merits of the book we have nothing but praise.

SURGICAL TREATMENT. (*b*)

It is about fourteen years since the first edition of this work appeared, and immediately received a hearty welcome from the surgical profession. It is now presented in a revised form with ample additions and such changes as are necessary to bring it up to date. The authors have adhered to their original plan of not overloading the book with all the methods of treatment described or even in use, but have made a wise and careful selection of those methods which they have proved by practical experience to be the best. The work appeals to the practitioner rather than to the student, and should be found useful for frequent reference by the general practitioner as well as by the practising surgeon.

The first volume contains five divisions, which treat of (1) Inflammation and its Sequlæ; (2) Wounds and their Complications; (3) Syphilis and Tuberculosis;

(*a*) "The Nervous and Chemical Regulators of Metabolism." By D. Noël Paton, M.D., B.Sc., Professor of Physiology in the University of Glasgow. London: Macmillan and Co. 1913. Pp. 217. Price 6s. net.

(*b*) "A Manual of Surgical Treatment." By Sir W. Watson Cheyne and F. F. Burghard. New edition, entirely revised and largely re-written with the assistance of T. P. Legge and Arthur Edmunds. In 5 volumes. Vol. i., pp. 552, figs. 223; vol. ii., pp. 598, figs. 252, plates 4; vol. iii., pp. 603, figs. 271. London: Longmans, Green and Co. 1912. Price 21s. net each vol.

(4) Tumours; (5) Deformities. There is also an appendix which deals with anæsthetics, both local and general, and the examination of the blood in surgical conditions. We would suggest that enough emphasis is not laid on the use of iodine in the preparation of the skin of the patient for operation, and even more in the treatment of accident and dispensary work, in which the introduction of the use of iodine has brought about what is little short of a revolution within the last five years.

The second volume, in its three divisions, deals with:—(1) The Surgical Affections of the Soft Tissues; (2) Of the Bones; (3) Amputations. In the section on the arteries and aneurysms, arteriorrhaphy and Matas's reconstructive method of treatment are fully described. In the section on fractures the authors do not advise operation for all cases, but state that it is not justifiable to leave the patient with an ununited or badly united fracture, or even a recent fracture in bad position, if the fragments can be maintained in proper position by means of an operation, and while they are not prepared to discard splints entirely they are of opinion that massage and careful passive movement may be associated with them to a far greater extent than has hitherto been the case, not only without risk to the union, but with actual advantage to the patient.

The third volume corresponds to Volume IV. and part of Volume V. of the old edition. It deals with affections of:—(1) The Joints; (2) The Spine; (3) The Head and Face. It has been brought thoroughly up to date and adequately and carefully revised. Various operative measures for unreduced dislocations, fracture dislocations, and recurring dislocations are very fully described. Of tuberculous diseases of the joints the authors say that operations "are diminishing in number every year." The description of arthroplasty is very meagre and the illustrations are difficult to follow owing to the misplacing of the two lower figures on page 154. The section on the treatment of affections of the head and face has been modernised, and there is a particularly good chapter devoted to the treatment of trigeminal neuralgia. The illustrations throughout all three volumes are numerous and at the same time good, showing clearly what is intended. Though the surgeon may not agree with all that is said in this work, he will find on all questionable points that the authors are "able to give a reason for the faith that is in them."

HÆMOCYTES AND HÆMIC INFECTIONS. (*a*)

This remarkable volume presents many of the characteristics of the work of an enthusiastic pioneer; thoroughly trained and equipped—in the most up-to-date modern methods, and for the extension of the borders of the daily expanding scientific domain. The author modestly disclaims all pretension to "a complete treatise." From the personal view-point we are very glad; too many complete treatises have passed through our hands in the past, and very nauseating—and all too imperfectly pre-digested—mental pabulum we found tinned, and stamped, and trade-marked, between their orthodoxically respectable covers. The micro-photograms form the outstanding feature of the work, and we congratulate the author on their production. They "have been taken at a magnification which would clearly set forth the morphological characters of cells and parasites as seen in the blood in various phases of disease." The great enlargement inevitably takes away from the diagrammatic clearness of the æsthetic marginal outlines of the illustrations of the older text-books; but they also make us recall the view so forcibly expressed by Macaulay, that caricature is the most impressive method of conveying knowledge—in history especially. The prevailing doctrine of bacteriological and protozoan pathology is well represented here; and even the inquiring heretics who believe those agents to be grievously libelled by the current orthodox acceptation of such as *causa causans,* will surely derive profit and pleasure from a perusal of Dr. Burnham's volume.

SLEEPING SICKNESS. (*a*)

The contents of this booklet represent the essence of the up-to-date scientific expression of the experts' view of the nature of one of the strangest of clinical entities. Statistical data are given, so that the reader is supplied with at least the broadly outlined arrangement of facts. Effect and (attributed) cause do not, perhaps, dovetail so perfectly as the logician—and philanthropist—would like. Perhaps the most interesting section, for many readers, will be that which tells "How the Brigade wages War against the Glossina Palpalis." When the animal pests have been exterminated, and the drainage and hygiene brought into line with modern achievement, there will surely be better health in tropical zones. And the indictment, even if proved absolutely false, will hardly carry unpopularity of the prosecutor. Did not the immortal Koch drag in the crocodile? And dreadful things have been said of recent years about the sanitary influence of the rat, and the flea, and the (still more familiar) house-fly! And most of us believe that we would be better without those neighbours, and will sympathise little with them, even under unjust accusation and punishment.

FOOD AND FEEDING. (*b*)

It is less than three years since the first edition of this invaluable text-book saw the light, and now that a second has been called for the author has brought it well up to date by the inclusion of a good deal of fresh material. Commencing with an account of the physiology of the digestive processes and the metabolism of the foodstuffs, the reader is led by easy stages to the detailed consideration of every article of food in common use and its effects upon the body in health and disease. Vegetarians, or at any rate those who believe that health and vigour of body can be maintained upon a diet that excludes flesh foods, will derive some comfort from the statement on page 522 that "it is certainly possible now to frame an exclusive vegetarian *régime* containing an adequate amount of proteins, fats, carbohydrates and salts, in which there is no excess of bulk of vegetarian foodstuff." On page 531, however, the author summarises the whole question by stating that "it may be said that in healthy subjects, and more especially in young subjects under forty years of age, a lacto-vegetarian diet has no advantages over the more conventional mixed dietary, taken in equal moderation and submitted to the process of thorough mastication; in later life, however, in health it is a wise rule gradually to more and more restrict the rich animal protein foods, and approximate to a lacto-vegetarian *régime.*" The term "alimentary toxæmia," nowadays so much boomed, does not find a place in the book, though reference is made in several chapters to the deleterious effects upon various systems of the body of poisons "absorbed from the alimentary canal." Intestinal auto-intoxication has a section all to itself (page 346).

Forced feeding (not "forcible") is described as being resorted to "in asylum practice and in certain medical affections of the tongue, pharynx and œsophagus which render deglutition impossible." The merits and composition of many so-called proprietary foods and beverages are freely discussed, as well as the circumstances in which they may be found useful. The practitioner will derive the greatest help from the

---

(*a*) "Hæmocytes and Hæmic Infections: A Handbook for Students and Practitioners." By Frederick W. E. Burnham M.D., C.M. With 226 microphotograms by the author. London: H. K. Lewis. 1913.

(*a*) "Sleeping Sickness in the Island of Principe: Sanitation, Statistics, Hospital Services and work of Official Conservancy Brigade." By Surgeon-Captain Bernardo F. Bruto da Costa Health Officer and Chief of the Sleeping Sickness Commission. Translated by Lieut-Colonel J. A. Wyllie, F.R.G.S., Indian Army (retired), Hon. Associate, Centro Colonial, Lisbon. Published for the Centro Colonial, Lisbon, by Baillière, Tindall and Cox, London. 1913.

(*b*) "Food and Feeding in Health and Disease." A Manual of Practical Dietetics. By Chalmers Watson, M.D F.R.C.P.E., Assistant Physician, Royal Infirmary, Edinburgh. Second edition, revised. Pp. xvi., 638. Oliver and Boyd: Edinburgh and London. 1913. Price 10s. 6d. net.

chapters upon the appropriate diet suitable for diseases of every organ and system of the body. Many excellent menus are given, while the directions given for making various articles for invalids are readily followed. In fact, Dr. Chalmers' book is a valuable one for cooks and nurses, and everyone who has anything to do with the sick should read Chapter XIII. on "The General Serving of Food for Invalids." A full account is given of the diet suitable for all stages of tuberculosis, and the specimen dietaries for patients at both extremes of the social scale are all that can be desired. An interesting section of the book is devoted to "Special Diet Cures," these comprising purin-free diets, Salisbury, milk and whey, and sour milk treatments. The Banting and Oertel systems are described in connection with obesity.

In the appendix, which occupies some sixty pages, will be found a valuable series of original papers by the author and other collaborators upon the influence of meat diet upon growth, the thyroid gland, the kidneys, and other organs. There is an unusually full index. After a careful examination of Dr. Chalmers' text-book we have no hesitation in pronouncing it to be the best of its kind in the language.

LITERARY NOTES.

Some useful therapeutic hints are to be found in No. 11 of *Riedel-Archiv*, a monthly supplement to the well-known "Riedels-Berichten"—"Riedel's Mentor," already noticed in our columns. Many of the preparations of the house of the J. D. Riedel Co., familiar to practitioners, such as gonosan, salipyrin, and neu-Bornyval, are the subject of interesting articles, and a capital photogravure of Gerard Dou's "The Doctor and his Patient" is presented with this number.

* * *

The current number of the *Prescriber* contains the usual therapeutic hints and notes that we are accustomed to look for in the pages of this up-to-date little monthly. In an editorial on the art of prescribing it is stated that "the art is not dead; it is merely asleep, and it lies with the profession to see that it does not oversleep itself." Where time is a consideration, as with many an overworked medical man, it is to be feared that the period of somnolence will be so prolonged that all desire to resume consciousness may be lost altogether.

* * *

"Minor Statesmen," reprinted from *Truth* (London: "Truth" Publishing Company, 1913), is further described on the title-page as "a series of complimentary calumnies on illustrious men, including Mrs. Pankhurst." Readers of *Truth* already know these clever, if light, character sketches of more or less prominent persons. The characterisations are on the whole good-humoured, though the humour is sometimes acid. In the case only of Mrs. Pankhurst has this acidity become vitriolic. The book is an excellent one for the railway carriage or the waiting-room.

* * *

Those parents who contemplate keeping careful records of the physical, mental and spiritual progress of their offspring will find the "Progress Book," a revised and enlarged edition of which has just been issued by the proprietors of Mellin's Food, Ltd., a valuable register for this purpose. It has been compiled by Dr. J. J. Pilley, Ph.D., and every phase of development is provided for from the time of birth until coming of age and after. Weight-charts, blank spaces for photographs at different ages, an autograph and finger-print register, are among the many interesting features of this interesting book which should be in the hands of every parent. It is published in different bindings at 1s. 6d., 2s. and 3s. We are requested to announce that a copy may be obtained by the first thousand readers of this Journal who will cut out this notice and send it with ninepence in stamps to the Secretary. Marlboro Works, Peckham, S.E.

MEDICAL NEWS & PASS LISTS.

Medical Sickness and Accident Society.

At the last monthly meeting of the Executive Committee of this Society, the claim account presented showed a decided reduction in the amount and was not above the expectation. New business was well above the number for the corresponding month in preceding years and is still rising. The increasing interest taken by the profession in the Society and the many inquiries received at the head office in Chancery Lane prove that the solid business basis on which this is run and the fair way in which all claims are met is much appreciated.

For 30 years now the Society has steadily progressed, and from quite a small concern has gradually developed into one of some prominence in the insurance world, with invested reserves of over £260,000. The Committee at this meeting discussed some changes of the rules which are to be submitted to the members at the annual meeting next year. It has been thought advisable to bring these more up to date and give greater facilities for dealing with sundry matters which from time to time have arisen in the past. The basis of the quinquennial valuation was approved, and it was resolved that this should be done by the actuary to the Society as before. The substantial bonuses paid to members insured for sickness benefit on their attaining age 65 has come as a pleasant surprise to many members, and it is confidently hoped to be able to maintain this during the next quinquennium.

Apothecaries' Hall Dinner.

The Governor of the Apothecaries' Hall, Dublin, Alderman McWalter, M.D., entertained a large company to dinner in the Hotel Metropole on the 29th November. The principal speaker was the Recorder of Dublin, who discussed the housing question in Dublin and its bearings on crime Among others who spoke were Sir Charles Cameron, the President of University College (Dr. Coffey), the President of the Royal College of Surgeons (Mr. Purefoy), the Vice-President (Mr. Dwyer), Dr. Rowlette, Mr. R. C. B. Maunsell, Dr. Hayes, Mr. Dodlin, Alderman Maguire, and Mr. Quaid, T.C. An excellent musical programme was rendered.

Complimentary Dinner to Sir Andrew Horne and Sir Robert Woods.

The Master of the Rolls presided over a large company which assembled in the Examination Hall of the Royal College of Surgeons in Ireland last Thursday, when a complimentary banquet was given in honour of Sir Andrew J. Horne and Sir Robt. H. Woods, who had recently conferred on them the honour of Knighthood. Some 150 were present, including Fellows of the two Royal Colleges, and members of the clerical, legal, and other professions. The Presidents of both Royal Colleges attended with the maces.

In proposing the toast of the guests of the evening, Dr. James Little said he had the opportunity of watching the career of these distinguished men from the moment when they put their first step on the professional ladder until they had attained the exalted position which they now occupied. The Government had very properly made recognition of the members of their profession. It was quite right that they should honour a profession which, in some respects, was not so well fitted for the rush of life as were other professions. Their profession did not afford the opportunities of amassing an immense fortune or of gaining that position in life which some men aspired to, but they had assembled to signify their concurrence in the choice of the Lord Lieutenant, and they thoroughly endorsed what he had done in recommending these gentlemen for the honour conferred on them. Sir Andrew Horne, as President of the College of Physicians, had discharged his duties with urbanity and tact, and as President of the College of Surgeons Sir Robert Woods had acquitted himself with marked distinction.

Sir Andrew Horne, in responding, said His

Majesty had conferred upon him a distinction which he never ambitioned and he never sought, but he thanked His Excellency for recommending his name. One of his greatest gratifications on receiving that distinction was the warm tributes he received from all his friends, and the fact that he had associated with him his old friend, Sir Robert Woods. It was a happy augury to find that night that the two Colleges of Physicians and Surgeons were now so intimately united.

Sir Robert Woods also acknowledged the great honour which had been conferred upon him. He would feel it incumbent on him to try to live up to the high ideal which Dr. Little had set before them.

An excellent musical programme followed.

Suicide of a Medical Man.

A VERDICT of "Suicide whilst insane" was returned at the inquest held last week on Dr. David Owen, a well-known medical practitioner, of St. Brelades, Pendlebury, who was found dead in bed with a wound in his groin.

The deceased, who was 49 years of age, had an extensive practice, and for some years had been the medical adviser of Messrs. Andrew Knowles and Sons, colliery proprietors. Recently he had seemed unduly depressed. His work seemed to have worried him, said the Coroner, and he felt he could not get through with it. On the 28th ult. he retired apparently in his normal condition, and the next morning he was found dead, the bed being saturated with blood. He had evidently divided a large blood-vessel in the thigh with a razor, which was found on a chair at the side of the bed.

Mr. Hugh Owen said that Dr. Owen, his brother, had suffered from Bright's disease for some years, and on the night before his death witness had arranged for a locum tenens to look after his practice. He had been subject to fits of depression, and early on Saturday morning, when asked if anything was the matter, replied from the bedroom that he was all right, but had not had a wink of sleep.

The jury and the Coroner expressed their sympathy with the doctor's relatives.

The Late Dr. Alabone.

THE funeral took place recently at Abney Park Cemetery, of Dr. Edwin W. Alabone, ex-M.R.C.S. Eng., of Highbury Quadrant. Deceased, who was 65 years of age, was a well-known specialist in the treatment of consumption and diseases of the chest, and patients came to him from all parts of the globe. Those who were in too weak a condition to travel were visited by the doctor, regardless of distance, and others in remote parts of the world needing his assistance were treated through the medium of correspondence. He also enjoyed considerable repute as a microscopist, botanist and painter.

The Hampstead Health Institute.

H.R.H. PRINCESS LOUISE, who was accompanied by the Duke of Argyll, opened last week the Hampstead Health Institute, which has been established in Kingsgate Road at a cost of over £3,000 as a memorial to King Edward. The Royal party were received by the Mayor and Town Clerk of Hampstead, the Bishop of Willesden, and others.

The Mayor of Hampstead, in moving a vote of thanks to the Princess, said the work of the institute would be divided into two parts, one comprising a school of domestic economy, with a clinic for children and various other social works, and the other the tuberculosis dispensary. In the clinic children would receive proper medical supervision from infancy until the time when they passed into the care of the medical officers of the London County Council.

Fire in a Hospital.

THE Durham County Hospital was the scene last week of a fire which originated in the linen room, and when discovered it had a good hold.

Fortunately 13 women and eight children were removed by willing helpers to a place of safety, but, owing to the hard frost, great difficulty was experienced in getting a good supply of water. Happily, the inmates, who numbered 50, were never in serious danger. The sitting-room, immediately above the linen-room, occupied at the time by the matron, was damaged, the flooring being burnt through. The Newcastle Fire Brigade was telephoned for, but local effort succeeded in extinguishing the fire.

The Death of Dr. Dimock.

IT is announced that Professor G. Sims Woodhead has received from the Home Office, in answer to his suggestion that a public inquiry should be instituted into certain circumstances attending the prosecution and death of the late Dr. Dimock, a letter dated November 26th, in which it is stated that the Home Secretary had no power to institute any inquiry at which evidence would be taken on oath or at which the matters mentioned could be satisfactorily investigated.

It further says that the Home Secretary had communicated with the coroner, as he thought it possible that the evidence Dr. Sims Woodhead wished to offer might be heard at the inquest, but he gathered from the coroner's reply that he was not likely to hold that such evidence would be relevant to the question of the cause of Dr. Dimock's death. In these circumstances Mr. McKenna, to his regret, was unable to take any further steps in the matter.

University of London.

THE following candidates have passed the third (M.B., B.S.) examination with honours:—Hugh J. O. Ewing (a, e, University Medal), Univ. Bristol; Henry L. H. Greer (e), Queen's Univ., Belfast; Alfred E. Hallinan (b), Charing Cross Hosp.; Leslie M. Ladell (a), London Hosp.; Alexander C. Palmer (e), London Hosp.; Charles E. Thornton (a), Middlesex Hosp. (a) Distinguished in medicine. (b) Distinguished in pathology. (e) Distinguished in midwifery and diseases of women.

The following passed (names arranged alphabetically):—John Appleyard, Cuthbert H. Attenborough, Margaret M. Basden, Alured C. L. O'S. Bilderbeck, George F. Bradley, Albert J. Clarke, Raymond J. Clausen, Frederick W. T. Clemens, John A. Cowan, Jules M. Curé, John P. Davies, Richard D. Davy, Sheldon F. Dudley, William H. Eggar, Pattie R. Elliott, Abraham S. Erulkar, Douglas M. Gibson, Cyril E. Goddard, Charles F. Hacker, Claude C. Harrison, George M. Heiron, Philip H. Henson, Melville Hocken, Thomas H. Holroyd, James M. Joly, William H. Jones, Thomas P. Kilner, William Leslie, Muriel A. Lloyd, Margaret J. McEnery, Guy Matthews, Henry B. Parker, Hilda M. Pollard, William J. A. Quine, Henry M. Rashbrook, Aneurin E. Roberts, Arthur D. Rope, Douglas Ross, Arthur L. Shearwood, Hector Smith, Ernest N. Snowden, Edward S. Sowerby, J. Vaughan-James, Harry B. Walker, Edgar W. Whiting, Gerald Whittington.

University of Cambridge.

AT a Congregation held on December 6th the following degrees were conferred:—

M.D.—J. W. Linnell, St. John's.

Sc.D.—A. S. F. Grünbaum, Caius.

M.B. and B.C.—H. W. Barnes, Jesus; V. F. Soothill, Emmanuel; W. A. Stokes, Emmanuel.

M.B.—G. M. Parker, Emmanuel.

Trinity College, Dublin.

THE following candidates have passed the final medical examination, Part II., Michaelmas Term, 1913:—

Midwifery.—Ernest E. Lavy (Clk.), William O. Tobias, Trevor A. Lawder, passed on high marks; Quentin V. Brook Wallace, James N. Armstrong, Frances S. Mitchell, George Buchanan, John G. Butt, Thomas D. Power, Robert J. B. Madden, Hamilton B. Goulding, Charles D. M. Buckley, William H. Elliott, Nicholas H. H. Haskins, Robert A. Anderson, Fredk. G. Beatty, Kathleen D. Wallace, Robert I. Sullivan, Eric A. Lumley, Edward Evans, Joseph P. Quinn, John C. A. Dowse, George H. Wood, Francis A. L'Estrange, George S. McConkey, Thomas J. L. Thompson.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Dr. L. M. (London, E.).—Resorcin should not be employed upon the scalp if the hair be fair, as an objectionable coloration may be imparted. Stains may be got rid of by bathing with a weak solution of citric acid.

Mr. P. R. (Surbiton).—The medicinal use of opium, hyoscyamus, aloes, crocus and fig extract were certainly known to the ancient Egyptians, and their success in the treatment of glaucoma and ophthalmia was renowned.

WORKMEN'S COMPENSATION ACT, 1906

The Home Secretary gives notice that in consequence of the death of Dr. Frank Buszard the appointment of Medical Referee under the Workmen's Compensation Act, 1906, for Ampthill, Brackley, Buckingham, Kettering, Northampton and Wellingborough County Courts is now vacant. Applications for the post should be addressed to the Private Secretary, Home Office, and should reach him not later than the 31st December, 1913.

M.R.C.S. (Devon).—Oxygen has been injected hypodermically for various disorders. The latest use of this remedy is announced by Dr. Toulouse, the director of the asylum at Vilejuif, who has employed it in cases of epilepsy, mania and melancholia with distinct benefit. Further details of the method will be awaited with interest.

Meetings of the Societies, Lectures, &c.

Wednesday, December 10th.

Plymouth Medical Society (Athenæum Chambers, Athenæum Lane, Plymouth).—8.30 p.m.: Paper:—Mr. R. Jaques: A State Medical Service.

South-West London Medical Society (Bolingbroke Hospital; Wandsworth Common, S.W.).—9 p.m.: Mr. P. W. G. Sargent: Some Common Affections of the Knee Joint.

Hunterian Society (St. Bartholomew's Hospital (Library), E.C.).—9 p.m.: A Series of Short Papers will be read.

Thursday, December 11th.

Royal Society of Medicine (Section of Surgery: Subsection of Orthopædics) (1 Wimpole Street, W.).—4.30 p.m.: Cases by Mr. C. Max Page, Mr. R. C. Elmslie.

Royal Society of Medicine (Section of Neurology) (1 Wimpole Street, W.).—8 p.m.: Clinical Meeting. Demonstration of Cases: Dr. Turney, Dr. James Taylor, Dr. F. E. Batten, Dr. James Collier, Dr. Purves Stewart, Dr. Farquhar Buzzard.

North London Medical and Chirurgical Society (Board Room of the Great Northern Central Hospital, Holloway Road, N.).—9 p.m.: Paper:—Dr. Constance Long: Treatment by Psychotherapy.

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.: Paper:—Sir Ronald Ross, K.C.B.: The Study of Infections byEnumerative Methods (illustrated by lantern slides).

Friday, December 12th.

Royal Society of Medicine (Section for the Study of Disease in Children) (1 Wimpole Street, W.).—4.30 p.m.: Discussion: On Enlargement of the Spleen in Children (opened by Dr. Robert Hutchison and Sir John Bland-Sutton). Followed by Dr. G. A. Sutherland and others

Royal Society of Medicine (Clinical Section) (1 Wimpole Street, W.).—8.30 p.m.: Cases by Dr. F. Parkes Weber, Mr. Arthur Evans, Mr. Thomas H. Kellock, Dr. Frederic S. Palmer.

Tuesday, December 16th.

Royal Society of Medicine (1 Wimpole Street, W.).—5 p.m.: General Meeting of Fellows: Ballot for Candidates for Fellowship.

Royal Society of Medicine (Section of Medicine) (1 Wimpole Street, W.).—5.30 p.m.: Paper:—Dr. F. W. Scott Macfie and Dr. J. H. L. Johnston: Experiments and Observations on Yellow Fever.

Appointments.

Barrington, F. J. F., M.S.Lond., F.R.C.S.Eng., Surgical Registrar to University College Hospital.

Clifford, Harold, M.B.Lond., F.R.C.S.Edin., M.R.C.S.Eng., L.R.C.P.Lond., Honorary Gynæcologist to the Salford Royal Hospital.

Fletcher, W. J., L.A.H.Dub., Certifying Surgeon under the Factory and Workshop Acts for the Stoney Stanton District of the county of Leicester.

Graham, Lewis, M.S.Lond., F.R.C.S.Eng., Honorary Obstetric Registrar to the Birmingham Maternity Hospital.

Hayes, J. G., L.R.C.P. & S.Irel., Clinical Assistant to the Chelsea Hospital for Women.

Mayne, W. H., M.B., B.Ch.,Dub., Certifying Surgeon under the Factory and Workshop Acts for the Warrenpoint District of the county of Down.

Vacancies.

Newcastle-upon-Tyne City Asylum, Gosforth, Newcastle-upon-Tyne.—Junior Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board and laundry. Applications to the Medical Superintendent.

Nottingham General Dispensary.—Resident Surgeon. Salary £220 per annum, with apartments, attendance, light and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

Northampton General Hospital.—Senior Resident Medical Officer. Salary £120 a year, with apartments, board, washing and attendance. Applications to C. S. Risbee, Secretary-Superintendent.

Joint Counties Asylum, Carmarthen, South Wales.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Corporation of Birmingham.—City Hospital, Lodge Road.—Assistant Resident Medical Officer. Salary £150 per annum, with board, residence, etc. Applications to the Medical Superintendent.

St. Bartholomew's Hospital, Rochester, Kent.—Resident House Surgeon. Salary £150 per annum, with board, residence, and laundry. Applications to Charles Speyer, Secretary.

West Ham Union.—Second Assistant Medical Officer. Salary £140 per annum, with the usual residential allowances. Applications to Thomas Smith, Clerk, Board Room, Union Road, Leytonstone, N.E.

Ashton-under-Lyne Union.—Assistant Medical Officer. Salary £150 per annum, rations, laundry, and residence. Applications to G. H. Partington, Clerk to the Guardians, Poor-law Offices, Ashton-under-Lyne.

Births.

Barendt.—On December 4th, at 65 Rodney Street, Liverpool, W., the wife of Frank H. Barendt, M.D.Lond., F.R.C.S.Eng., of a son.

Davidson.—On December 4th, at 5 Western Parade, Southsea, the wife of Maurice Davidson, M.D., of a daughter.

Folliott.—On December 3rd, at 67 Weymouth Street, the wife of Fleet-Surgeon E. Folliott, R.N., H.M.S. "Iphigenia," of twin sons.

Kennard.—On December 4th, at 12 Bedford Square, W.C., the wife of Dudley Kennard, F.R.C.S., of a daughter (stillborn).

Leaning.—On November 28th, at Cromwell House, Gunnersbury, W., the wife of Dr. R. Craske Leaning, of a daughter.

Lucas.—On December 5th, at 19 Westbourne Terrace, the wife of Nathaniel S. Lucas, M.B., of a daughter.

Marriages.

Crossle—Du Bedat.—On November 22nd, at Holy Trinity Church, Killiney, Co. Dublin, Captain Howard Crossle, I.M.S., fourth son of the late F. C. Crossle, M.B., of Newry, to Mary Rosa, younger daughter of F. E. and the late Mrs. Du Bedat, Willmount, Killiney.

Deaths.

Jones.—On December 7th, at 109 Drakefield Road, Balham, Sydney Jones, M.B., F.R.C.S., in his 83rd year.

Price.—On November 28th, at Carmarthen, Rees Griffiths Price, M.D.Durh., L.R.C.P. and L.M.Edin., L.F.P.S.Glasg., aged 66.

Walker.—On December 4th, at 206 Peckham Rye, S.E., Josiah William Walker, M.D., in his 81st year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, DECEMBER 17, 1913. NO. 25.

NOTES AND COMMENTS.

Medical Man Vindicated. Of all the risks run by medical men in their professional work, few are so insidious or fraught with such damaging consequences as that of a false accusation of crime levelled at them by weak-minded or designing individuals. Thus a charge of assault is not infrequently preferred against a medical man by an hysterical or emotional woman after a physical examination has been made, more particularly when no third person has been present during the consultation. It cannot be too strongly emphasised that a third person should invariably be present during the medical examination of a female patient by a male practitioner for the protection of the latter, though there may be exceptional circumstances when this is not possible nor desirable. The hearing was concluded on Monday last before Mr. Justice Lawrence and a special jury of a case in which the plaintiff, a girl of eighteen, suffering from dysmenorrhœa, sued Dr. J. D. Bridger, of Willesden, for assaults alleged to have been committed by him on three occasions at his surgery. The defence was that after the patient's consent had been obtained and medicine had been given a properly conducted examination was made on two occasions. The patient's mother was said to have attacked Dr. Bridger with a dog-whip several times and to have behaved in a very excited manner in his surgery before other patients. As the learned judge remarked, to get her daughter to pose for photographs to be handed to the papers was not good taste, and to publish to the world her daughter's charms was evidence of a highly excited and ill-balanced mind. The child of such a mother might easily have wild and fantastic imaginings. A verdict was ultimately given for the defendant, and Dr. Bridger may be congratulated upon the satisfactory issue of a very trying ordeal.

The Motor Traffic Danger. THE danger of motor traffic in London is increasing year by year. The problem has aroused general attention, yet the toll of accidents and the death-roll show a steady upward curve. It is agreed on all hands that something must be done to protect the public, but the pity of it all is that no one appears to be able to suggest any really practical remedy. One of the chief disturbing elements is the widely differing rates at which wheeled traffic proceeds through the streets. Horses are disappearing fast, and in a few years' time nine-tenths or more of the vehicles will, in all probability, be mechanically propelled. Some of the ways in which greater safety may be secured seem fairly obvious, such as, for instance, subways for pedestrians at crowded parts, speed regulations, tests of physical fitness for chauffeurs, and so on. The real safety ideal, however, has yet to be discovered. Possibly London may learn something from Germany, where, in spite of multitudinous bye-laws, the protection of the citizen is secured in solid, Teutonic fashion.

How Berlin Goes to Work. As a matter of statistics, in Berlin 56 persons were killed and 2,700 injured per million residents during the year 1912. Greater London, on the other hand, shows no less than 76 killed and 2,700 injured per million residents. Next comes the interesting statement that the average number of journeys per head of population in London aggregate 230 per annum, whereas in Berlin they exceed 300. What do these figures mean? After allowing fully for the fallacies of figures, it seems clear as daylight that the Berlin traffic is considerably less dangerous to the public than that of London. One significant fact is that London, the more dangerous, possesses 1,500 tramcars and 3,000 motor buses, while Berlin, the less dangerous, has 3,000 tramcars and only 200 motor buses. Another pregnant fact is that Berlin has a central board of traffic control, in which each city and suburban district has a proportionate control. The German ideal, moreover, is that of wide streets with parallel ways, wherever possible, for traffic of varying speeds. Why should not London have a strong central traffic board and a greater proportion of tramcars to motor buses, if by such means her streets can be rendered as safe as those of Berlin? Why not?

Radium for Hospitals. THE use of radium in the treatment of certain forms of malignant disease may be said to have passed into the realms of practical therapeutics. A hospital without radium may, therefore, be considered, not only as being behind the times, but also as neglecting to provide one of the most modern weapons in the treatment of its patients. The plea of expense may well be urged by those hospital authorities who are not yet in possession of a few grains of the precious metal. To meet this legitimate objection, the important announcement was made the other day at the quarterly meeting of the Governors of the Middlesex Hospital by Prince Alexander of Teck that he had made a suggestion to the Council of King Edward's Hospital Fund with the object of securing a more economical provision of radium for use in the London hospitals. In order to avoid the capital account of these institutions being drawn upon for this purpose, he has asked the Council to consider whether they could purchase a quantity of radium, and allow all the London hospitals to utilise the emanations which could be collected from it at the price of their production. If such a scheme were adopted, the cost of radium treatment would be reduced tenfold. His Royal Highness has, moreover, offered, on behalf of the Middlesex Hospital, to arrange for the preparation of these emanations in their Cancer Research Laboratories, so that the various hospitals participating in the scheme could obtain tubes of the emanations at a price extremely small compared with the cost of purchasing them in the open market. Such a method for obtaining radium seems a very sensible one, and it is to be hoped that the scheme may commend itself to the managers of the King Edward's Hospital Fund.

The Tortoise Bacilli Boom.

THE history of medicine presents a strange medley of superstitions, fads, fashions, South Sea bubbles, personal booms, mingled with a vast redeeming amount of devoted searching after truth, and here and there a solid stride ahead in scientific knowledge. After all said and done, the world owes an untold debt to the humble and ill-requited toilers after truth, who have done more to better the lot of mankind than all the soldiers who have fought for less noble purposes since man first evolved into an animal capable of using arms and of organising armies. To turn from this picture to that of a German medical man who, by all accounts, has reaped a huge fortune in America from an alleged cure for consumption is, indeed, to look upon a counterfeit presentment—two brothers of widely differing character. Dr. Friedmann's curative tortoise serum was not accepted by the orthodox medical profession in the United States, but that fact apparently did not prevent its adoption by a heavily capitalised commercial syndicate. Dr. Friedmann has since returned to Berlin and, according to recent reports, has at last consented to permit his serum to be used by all German physicians. It seems clear that, even under the most favourable circumstances, a long time must elapse before medical experts will be enabled to arrive at definite conclusions as to the value of the remedy, which nevertheless created a record "boom" in the United States.

LEADING ARTICLES.

THE DISCOVERY OF THE LIFE CYCLE OF THE ORGANISM OF SYPHILIS.

THE discovery of the specific pathogenic organism of syphilis by Schaudinn in 1905 constituted a great landmark in the history of medical science. Naturally, an advance of that importance stimulated further research in all parts of the civilised world, and this culminated in 1912 by the publication of an article in the *Lancet* of October 12th, by Mr. J. R. McDonagh. The gist of his communication was that the spirochæta pallida was an adult male, that there was also a female, and that spores resulted from the fertilisation of the latter by the spirochæta, and that these spores were able to start another life cycle. McDonagh's article of October 12th announced a great scientific observation. It was followed by a correspondence that hinted rather than directly claimed priority of discovery on the part of Mr. E. H. Ross. As the matter is one of great interest to the medical world, we have thought it right to examine the facts with a view of settling the question of originality once for all. On October 19th a letter appeared in the *Lancet* from Mr. H. C. Ross, stating his opinion that Mr. McDonagh had rather jumped to conclusions, and that he founded that view on the strength of work done by E. H. Ross and Dr. W. Cropper in the McFadyean Research Laboratories. By the well-known jelly method his brother had demonstrated in a protozoal parasite in the lymphocytes of a guinea-pig a final transformation into free swimming sprochætes. Cropper discovered a similar organism in the cells of the vesiculæ seminales of earthworms. Mr. H. C. Ross admitted that his brother, E. H. Ross, had obtained material from McDonagh at the Lock Hospital which he had visited for the purpose. He added that his brother had there informed McDonagh as to his researches. At the same time he admitted that McDonagh gave his brother some slides which he stated show "splodges" in the cells. This letter called forth a prompt answer from McDonagh, who wrote on October 26th stating that his special investigations began in January, 1912: that E. H. Ross came to the Lock Hospital on September 14th, and was informed of McDonagh's finding certain bodies in infected lymphatic glands, and of the latter a specimen was given to Mr. Ross. On September 28th, Sir Ronald Ross wrote to the *British Medical Journal*, saying that his brother, E. H. Ross, had found bodies in syphilis "not in the mononuclear leucocytes of the blood, but in large mononuclear cells squeezed from local lymphatics." It is thus evident that E. H. Ross obtained syphilitic gland tissue and slides from McDonagh on September 7th, and a week later his brother is claiming for him credit for an observation derived from a study of gland tissue furnished by McDonagh who also supplied microscopic slides and an account of his special observations. McDonagh, moreover, had directly studied the living organism, and, amongst other things, saw the act of impregnation. He has pointed out that Ross used the jelly method, which at once kills the organisms, whereas his observations were made on the live bodies stained by borax methylene blue. Moreover, the original stain used by Ross was Azur II., which has no metachromatic properties, but later polychrome methylene blue was employed, which is to all intents and purposes the same stain as borax methylene blue used solely by McDonagh for his *in vivo* study. As the jelly method kills the organisms, Ross was unable to witness impregnation, and hence could not say which body was or was not the female. Then, again, McDonagh published an illustration of the life cycle of the male and female organism, which formed part of a paper read before the Pathological section of the Royal Society of Medicine, December 3rd, in the *Lancet* of December 14th. Ross followed with his drawings in the *British Medical Journal* of December 14th, 1912. Since then some illustrations by Ross have been published in Castellani's book on "Tropical Diseases," but his picture differs materially from that figured by him in the above-mentioned article, the chief difference being that the bodies in the second case were arranged in a scheme resembling that of McDonagh's. All this internal evidence points to McDonagh as first in the field. Ross, indeed, has not entered the lists in person, but he or his friends, in order to establish any claim to priority, will have to show (a) that he did not obtain material and special information from McDonagh; (b) that he examined the organisms *in vivo*; (c) that he witnessed impregnation; (d) that McDonagh's sections in his possession show nothing more than "splodges"—*i.e.*, they do not illustrate the changes decribed by McDonagh. The coloured plates and photographs of nearly every phase, which were made from sections, and which illustrate McDonagh's article in the *Dermatologische Wochenschrift* Bd. 56 S 413, 1913, do more than depict "splodges." In fact, it is doubtful whether finer photographs of organisms than these have ever yet been printed. It appears that in a recent number of the *Biochemical Journal*, October, 1913, McDonagh has even worked out the chemistry of the various phases of the life cycle of the syphilitic parasite. Such a feat has never been achieved before; its importance is of the greatest magnitude, since it opens up an entirely new field for medical research. Most candid critics will probably agree with us that on the facts cited the weight of evidence is overwhelmingly in favour of McDonagh. British dermatology has long been dwarfed and discouraged by the internal jealousies and petty spitefulness of its self-constituted leaders. It would be a great pity if the only great discovery that has been made in that special study for a generation or more should be minimised by an ungracious and, so far as can be judged, a groundless claim for priority. In our opinion, the honours rest indubitably with McDonagh as first in the field both in discovery and publication.

GONORRHŒA IN ITS MODERN ASPECTS.

Now that the Royal Commission upon Venereal Diseases has been appointed the appearance of an authoritative book upon gonorrhœa is opportune, and it may be well in introducing Luys' book (*a*) to the notice of our readers, to say a few words concerning a hitherto much neglected subject. Lest a false notion should be suggested by a reference to the Royal Commission, it may be at once surmised that its labours will end in naught, simply sharing the fate of, say, some eighty or ninety per cent. of previous official investigations of a similar kind. We have little hesitation in predicting that the Royal Commission upon venereal diseases is foredoomed to absolute failure so far as actual practical achievement is concerned. Moreover, there is reason for thinking that those who brought it forward anticipated no other result than extinction by exhaustion, just as in the case of the inquiry into patent medicines and quack practice. At the same time, it is clear that an extremely valuable function may appertain indirectly to such an investigation, namely, that resulting from the education of the public. The importance of the bearing of gonorrhœa upon the general health has long been recognised by medical men, and its serious aspects are now much more widely recognised. The discovery of the relation of the gonococcus to conditions of the female pelvic organs demanding grave surgical operations constituted a new era in gynæcology. Nor has the full significance of gonococchæmia and gonococcal joint affections been yet grasped from a preventive and curative point of view. It is obviously impossible within present limits of a brief notice to discuss the subject adequately even in its broader aspects. Every medical practitioner will do well to study the scientific aspect of the malady, as he cannot fail to find matter of everyday interest, whatever may be his field of practice. A generation ago gonorrhœa received scant attention, whereas nowadays it taxes our best scientific resources. It is no longer customary to dismiss a patient with a prescription for an injection and directions to procure a supply of capsules of santal wood or copaiba oil. Turn to page 374 of Mr. Arthur Foerster's excellent translation of Luys' book and we find a concise *résumé* of the general lines of treatment in chronic urethritis. At the outset, it is stated, "urethro-vesical irrigations diminish the intensity of the inflammation. As soon as possible one combines them with massage of the glands connected with the urethra (prostate, seminal vesicles, Cowper's glands). When all inflammatory symptoms have disappeared, slow, methodical and far-pushed dilatation of the urethral mucuous membrane is indicated. Once it has reached a certain degree, urethroscopy can be applied without difficulty. It enables one to tell if there are any diseased patches left which require special treatment (dilatation of the highest degree). Once the latter has done its duty, a new urethroscopic examination is necessary, and on the finding which it yields will depend the choice of further treatment by intra-urethral applications of the galvanic cautery, electrolysis, and so on." All this points to a rational and expensive scheme of therapeutics in gonorrhœa. Some day the vaccine therapy of the disease may be converted into a rapid and trustworthy method of cure. Even now it has greatly increased our control over the risks ensuing from secondary infection. So far as preventive measures are concerned it seems unlikely or, indeed, impossible from the essential circumstances of the case that compulsory notification can ever be applied to gonorrhœa. It may well be, however, that the law will render it a punishable offence knowingly to communicate the disease to another person.

(*a*) "Text-book of Gonorrhœa." By Dr. G. Luys, translated by Arthur Foerster, M.R.C.S., L.R.C.P. Baillière, Tindall and Co.

CURRENT TOPICS.

The Prescription.

The power of the prescription is not what it was. A few decades ago it was almost the end instead of the means of medicine. At a consultation the ceremony of "writing the prescription" was the climax. A table, with new pens and the other paraphernalia of orthography, was prepared. The physician carefully wrote the mystic script in sonorous Latin with a drug for every symptom and some extra ones thrown in to fill up the page and a few more added as correctives of the rest. The well-being of the prescription was hardly second to that of the patient. Now we see a difference. When the drugs are not incompatible the expressions used in their demand certainly are. A curious mixture of passable English and impossible Latin with a dash of trade names in no language on earth is presented to the pharmacist. Roman numerals used for easy numbers and Arabic for difficult ones like "48" are found jogging one another on the same sheet. The whole thing is unscholarly and slipshod, and not likely to make a favourable impression on an observant public. Besides being a disgrace to our profession, our slovenliness is reacting on the chemists, who are seriously considering whether or no Latin shall continue to be compulsory in their curriculum. The doctors no longer write Latin, so why should the chemists trouble to learn it? As a test, write

℞ Tr. Scillæ
Syr. Ejusdem

take the slip to the nearest chemist, and it is long odds that he will tell you that he has not got the second ingredient.

Sport and Health.

In view of the great prominence given to sport in our modern educational system, the question naturally arises as to what may be the ultimate effect of such training upon the national physique. Not every boy who has excelled in sport in his schooldays becomes a champion athlete in after-life, for circumstances may completely put a stop to further indulgence in his favourite game or pastime. Is the value of athleticism to the individual over-rated? Sir Thomas Oliver, M.D., in a lecture upon "Medico-Social Problems from an Insurance Point of View," delivered at Newcastle the other day, stated that athletic exercises possessed certain physical advantages, such as bracing a man up and making him more resistant to fatigue, but that they did not confer immunity against disease. It is a well-known fact that it is frequently the healthiest-looking men and women, also the most florid, who succumb most readily to fever, or to acute illness. Heart disease and tuberculosis are not unknown among sportsmen. As a matter of fact, hard athletic exercise is not the best training for young men who are destined for office-life or for some sedentary occupation. While it may be true that the symmetry of a well-trained body may command admiration, it remains a question whether the more perfected anatomical form renders an individual proportionately more able to cope with disease than his less muscularly developed colleague. It has yet to be demonstrated that the pupils of those schools where physical prowess is deified are more long-lived than those trained in colleges where such exercises are kept within moderate bounds. One of the most useful branches of physical exercise, and the one to be encouraged on account of the discipline associated therewith, is military training, which provides that co-ordination of physical and mental self-control that characterises the best type of manhood.

Celluloid Dangers.

Public attention has frequently been called to the dangers connected with the use of such an inflammable article as celluloid. Since its invention in 1869, the use of this commodity has steadily increased, more especially in connection with the preparation of cinematograph and other films. It will be remembered that a Departmental Committee was appointed in October, 1912, "to inquire and report as to the precautions necessary in the use of celluloid and celluloid articles." This Committee has now issued its report. Special attention is drawn to the conditions of storage of cinematograph films, the celluloid employed for the preparation of which is said to be more highly nitrated than ordinary celluloid, and therefore more inflammable. The regulations of the Cinematograph Act, 1909, are, on the whole, sufficient to ensure the safety of the public in places where films are exhibited, and certain concessions are properly made where the so-called "non-inflammable" films are in use. It is in film stores that a greater system of inspection appears to be needed, the more so because many of the premises in London are crowded together in narrow thoroughfares in the neighbourhood of Charing Cross Road. The festooning of films in shop windows is a practice which is quite inexcusable and should be absolutely prohibited, and it is satisfactory to note that such exhibits are repudiated by the regular trade. The Committee states that the sale of toy machines, as well as strips of disused films, to children containing no safeguards against fire should be prohibited. As regards articles of apparel manufactured from celluloid, such as buckles, combs, cuffs and collars, it is suggested that they should not be sold to the public without some clear indication of their real nature being given. It is to be hoped that the recommendations of the Committee will be enforced by all local authorities.

Subjects for Post-Graduate Study.

It is not always an easy matter for deans and secretaries of medical post-graduate colleges to arrange a course of lectures or demonstrations for medical men that will prove really helpful to them in their daily practice. A series of lectures dealing with the different aspects of some common disease is far more useful to the majority of practitioners than one treating of some rare affection little likely to be encountered by anyone except a specialist. In some colleges, the plan of holding a course upon certain special diseases, such as syphilis or tuberculosis, dealt with from every conceivable standpoint so as to interest medical men in every department of practice, has proved a great success. A post-graduate course on the feeding and care of infants, with special reference to the milk supply, has been arranged by the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy. It is to be held in the New Year, from January 12th to the 22nd, at various centres. The programme, which is most comprehensive, includes such subjects as the physiology of lactation, the bacteriology of milk, nutritional disorders of childhood, and other topics related to infant care and feeding. Certain of the day courses are open to non-medical persons, such as nurses, health-visitors, and others. For the modest sum of one guinea a complete symposium on infant feeding can be gone through with, extending over a period of ten days, with three or four sessions a day. Further particulars may be obtained from the Secretary of the Association, 4, Tavistock Square, London, W.C. It only remains to add that the advisory committee for the special course consists of men whose names are a household word among the profession.

The Unprotected Hatpin.

Few women realise the murderous character of the sharp points that gaily project from beyond the margin of the hats covering their unsuspecting crania. Thus protected, or adorned, according to the mental attitude of the wearer, the average woman will take her place among a throng of people waiting, perhaps, to board a tramcar, little thinking of the risks run by both sexes from being hustled and jostled together in such company by the sudden movements of the car. Now that small hats are the fashion, the peril is all the greater to passengers in public conveyances from this source. A warning notice was posted in all the London County Council tramcars last week directing the attention of lady passengers to the danger to their fellow-travellers and to the Company's servants of wearing hat-pins with unprotected points. This mild announcement may cause a slight sensation for a time, but it would be more to the point, literally, to prohibit the use of unprotected hat-pins altogether, as has been done successfully by the new Prefect of Police in Paris. It ought not to be impossible to provide that the points of all hat-pins shall be suitably protected by sheaths, which, in fact, are already sold by milliners for the purpose, in the case of female passengers by any public conveyance. Until the travelling public be adequately safeguarded from injury, the conductors of omnibuses and trams, and the guards of trains, might well be provided with a supply of corks, which could be made quite ornamental, wherewith to shield a particularly murderous-looking point. But perhaps the cost to the respective companies would be too prohibitive. No doubt good sense and decorative art will rise to the occasion.

The British Medical Association and Ireland.

The recent decision of the British Medical Association to increase its subscription to two guineas is likely to have important effects on its relation to the profession in Ireland. The causes which have led to the necessity for such an increase have had to do almost altogether with the interests of the profession in Great Britain. The problems facing the medical profession of Ireland under the Insurance Act are very different from those with which the Association has been mainly concerned, and whether any great political change in the relation of the two countries takes place or not, this difference is likely to persist. From the vast expenditure of the last few years the Irish profession has profited little, and, as a consequence, medical men in Ireland show little inclination to dip their hands deeper in their pockets. It must be admitted also that for many years past there has been a growing discontent in Ireland with the attitude of the official journal of the Association toward that country. We need not go into the reasons of that discontent, but that it is there is beyond question. The inevitable result of the present position will be that many members of the Association resident in Ireland will cease to subscribe. We do not think that the proposed establishment of a branch office in Ireland will have much effect, nor do we think that the Association can ever hope to be a representative organisation of the profession in Ireland. A unique opportunity is hereby opened to the Irish Medical Association to become a thoroughly representative body, and to embrace in its ranks the great bulk of the medical profession of Ireland. We are glad to know that several influential members are fully alive to the possibilities of the situation.

PERSONAL.

H.M. the Queen visited the Derbyshire Royal Infirmary last week, spending some time in the wards of the institution.

Dr. R. A. Fleming, M.A., M.D., F.R.C.P.Edin., has been appointed Physician to the Edinburgh Royal Infirmary.

The title of Reader in Pathology has been conferred upon Dr. William Hunter, of Charing Cross Hospital Medical School.

Mr. Lewis Graham, M.S.Lond., F.R.C.S.Eng., has been appointed Honorary Obstetric Registrar to the Birmingham Maternity Hospital.

Dr. H. W. Catto has been selected for appointment as an Assistant Bacteriologist and Pathologist in the Medical Department of Jamaica.

Mr J. J. Guthrie Blandford, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Superintendent of the Whalley Asylum, Lancashire.

Professor C. J. Martin, F.R.S., D.Sc., M.B.Lond., F.R.C.P., has been appointed President of the Section of Physiology of the British Association for the Australian meeting in August next.

Dr. T. Knowles Boney, of North Finchley, has been awarded the Savill prize and medal at the West End Hospital for Diseases of the Nervous System for his thesis on "Myasthenia Gravis."

Dr. D. J. Clark, of the Park Hill Sanatorium, Liverpool, and Dr. W. C. D. Hills, of the Sowerby Bridge Tuberculosis Dispensary, Halifax, have been appointed tuberculosis officers to the Kent County Council.

Major R. J. Blackham, R.A.M.C., Honorary Surgeon to the Viceroy, who is the Assistant Commissioner of the St. John Ambulance Brigade in India, was the recipient recently of an address of congratulation from the Bombay corps of the brigade on his being created C.I.E. The address was enclosed in a beautiful and valuable silver casket.

The Council of the Royal College of Surgeons of England have appointed Mr. D'Arcy Power, F.R.C.S., Surgeon to St. Bartholomew's Hospital; Mr. F. Richardson Cross, F.R.C.S., President of the Ophthalmological Society of the United Kingdom; and Mr. S. G. Shattock, F.R.C.S., Pathological Curator of the Museum of the College, to give evidence before the Royal Commission on Venereal Diseases.

FRENCH CLINICAL LECTURE

ON

DEFENSIVE REFLEXES: THEIR SEMEIOLOGICAL AND PROGNOSTIC VALUE.

By Dr. HENRI CLAUDE,

Professeur Agrege de la Faculte de Medecine de Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE interest attaching to the study of tendinous and cutaneous reflexes in clinical neurology is well known to all. The variations of these reflexes enable us to affirm the existence of a suspected organic lesion, and to distinguish it from a purely functional neuropathic trouble; also to localise the irritative or destructive alteration. The names of Westphal (1875) Vulpian, Strumpell, and Babinski are inseparably attached to the history of these signs, of which the importance is really so great that we have some difficulty in conceiving how, forty years ago, anyone could have ventured without them to enter the labyrinthine maze of nervous symptomatology. In these later times, on the other hand, the number of those reflexes has been multiplied to infinity, and the excessive zeal of the explorers has somewhat clouded the clarity of this department of semeiology. An exception may well be made to this general observation, with regard to the reflexes which have been called defensive; of which the determination preserves a very real value.

The classical experiment, of section of the cervical medulla in the frog producing a hyper-excitability of the limbs, had long before attracted the attention of physiologists. In the department of clinical neurology, A. Thomas has pointed out in a recent article ("La paraplégie spasmodique avec contracture variable."—*La Clinique*, 20, 27 juin, 1913) the existence of reflex movements of defence in many cases—notably in a case of paraplegia with flexure. Charcot had made the same remark. Brown-Sequard gave a specially detailed description of such phenomena in certain paraplegics; which are independent of the will, and are provoked by the slightest stimulation of the integuments. Finally, Vulpian studied these muscular contractions with the greatest care from the physiological view-point; so that we may well—with A. Thomas—be surprised that those great observers had not been remembered by contemporary authors.

Let us now see how those defensive reflexes display themselves—taking, as a typical case, one of Pott's disease in the lower dorsal region. The patient is incapable of any spontaneous movement; he is anæsthetic as high as the middle of the abdomen; the tendon reflexes may be either exaggerated or feeble. If we stimulate the skin of any part of the lower limbs by pricking or pinching, we see the following series of movements, which are all the more surprising on account of the presence of complete motor and sensory paralysis: Hyper-extension of the toes, and, above all, of the great toe; flexion of the foot on the leg, of the leg on the thigh, and of the thigh on the pelvis. The combination of those movements, which sometimes result slowly, sometimes very suddenly, represents a co-ordinate act of retreat of the limb, which flies, as it were, from the source of irritation. In some patients, the first stage of the reflex movement consists of adduction of the thighs; more rarely, there is abduction on one side; finally, in certain cases, to which we shall again refer, there is no retreat of the limb, but extension.

As a rule, the slightest stimulation of the skin suffices to produce the reflex movement. One of my patients presented those movements on the slightest shaking of his bed; also hearing the noise of a door somewhat violently closed, at a distance. Sometimes vigorous pricking or pinching of the skin is necessary to produce a complete retreat of the limb; less than this gives only a slight imitation of such, or merely a movement of the toes or of the foot. Generally, the intensity of the movement of retreat is proportional to that of the stimulation. In certain cases, stimulation of the skin of the abdomen, or even of that of the thorax, gives the same effect. Thus there is a whole tegumental territory, well defined, stimulation of any part of which produces the reflex movements. Constriction of the limb, pressure on the muscular masses, forced flexion of the toes and constriction of the metatarsus (Marie and Foix), forced supination of the forearm (H. Claude), passage of an electric current, hot or cold applications, irritation of the urethral or rectal mucous membranes, have the same effect. I have noted the undefinable sensation of malaise which patients usually feel during those tests. One who was completely anæsthetic declared that he experienced a sensation of pain when the retreat movement of the limb was produced by pinching; he was not able to localise it, but it had a quite special agonising character that was very difficult to describe.

These defensive phenomena are also observed in patients who are not paraplegic or anæsthetic, and have a wholly special diagnostic value; although the experiment is less demonstrative than in the completely paralytic cases: at the beginning of compressions of the cord, the diminution of strength is sometimes accompanied by exaggeration of the tendon reflexes, of the toe-phenomenon, and a special painful sensibility to pressure of the skin; accompanied by retreat of the limb. When the patient is questioned about the character of the pain which he feels, it is found that above a transverse line corresponding to the seat of compression, pinching of the skin produces a sensation which is merely disagreeable. But below that level, over all the inferior surface of the body, he experiences a truly agonising pain, accompanied by redness of the face and various emotional reactions.

It seems that the so-called *spontaneous* movements, accompanied by painful cramps, of which paraplegic patients often complain, present some analogies with those defensive movements. In fact, when we remember how slight and superficial the peripheral stimuli of the integument may be which provoke those movements of retreat, it would appear that the cause of the movement has possibly escaped the patient; and provoked a movement which appeared to be spontaneous.

The so-called defensive movements are not confined to the lower limbs; they can be produced in the upper limbs in cases of quadriplegia, in the way referred to above; by stimulation of a portion of the limb, especially by forced supination of the forearm, or pinching the cervical region. The movement consists at first of flexion of the wrist with slight adduction; flexion of the forearm on the arm, with pronation; and, finally, abduction of the arm. They are also produced in some cases of hemiplegia—but only in certain forms; they are provoked by non-destructive lesions of the pyramidal tract, cerebral œdema, a juxta-pyramidal focus of hæmorrhage or softening, cerebral tumour, meningeal hæmorrhage, etc. This is the phenomenon which I described, in 1900, under the name of *reflex hyperkinesis* in hemiplegia, and to which I attach a favourable prognostic significance; from the fact that, in my opinion, it indicates the existence of compression or irritation of the superior fibres of the motor tract, and not a section of this same.

An important point which it is desirable to place in relief in the clinical study of these phenomena of defence, is that: the movement of the several segments of the limbs which is produced by the stimulation is always repeated under the same form in the same patient, according to the area stimulated (Vulpian). When we pinch the skin about the ankle or the calf, we produce, according as the stimulus is more or less intense, extension of the toe and flexion of the foot; or, indeed, retreat of the whole limb. In another area, another movement is provoked by the same stimulus. P. Marie and Foix saw a patient in whom stimulation of the leg elicited a brusque movement of retreat, while extension of the whole limb followed pinching of the skin of the front of the thigh; or, if flexion occurred, it was always incomplete. I have a patient who presents rigidity in the position of extension, and very strong reflexes, in whom slight stimulation of the skin of the leg provoked bilateral extension of the toes; while pinching of the thigh caused adduction of the two limbs, with a movement of retreat of the stimulated one. The flexion of leg and thigh was incomplete, and could be obtained only by very strong stimulation. A patient of A. Thomas presented first an elongation of the limb (plantar flexion of the toes and extension of the leg on the thigh) on stimulation of the outer surface of the thigh in the middle third; this movement was barely carried out when it was succeeded by one of shortening or flexion. P. Marie and Foix think that from the distal to the proximal portion of the limb, stimulation produces reflex movements which vary according to the level of the segment excited. Symmetrical stimuli do not always produce the same reactions in the two corresponding limbs; and we can readily conceive that they may not behave in the same way, inasmuch as the central alterations are not always equal, and of the same nature, on both sides.

Another curious manifestation is the production of centro-lateral phenomena. As a rule, stimulation of a limb produces in the opposite one an outline of a movement of defence, as in extension of the toe and flexion of the foot; in some very slight cases, I have seen stimulation of the right side produce extension of the toe on the left side only. In A. Thomas's patient, pricking of the left leg provoked extension of the toe and retreat of the limb, on the left; while on the right side was seen plantar flexion of the toes, followed by extension of the foot on the leg. The inverse result followed stimulation of the right leg. Pierre Marie and Foix admit that, in some cases of paraplegia, forced flexion of the toes of one side causes retreat of the limb; while it provokes extension of the other limb when the stimulus is sustained.

Such are the principal forms in which the so-called reflexes of defence manifest themselves. We shall examine in further detail the very numerous varieties reported. It is equally impossible to linger over the relations which these may present in regard to the phenomena of sensibility. In cases of Brown-Sequard's syndrome, Babinski, Jarowski and Jumenti, and H. Claude have seen the defensive reflexes more pronounced on the anæsthetic side; Guillain has observed the reverse; Brown-Sequard, in his experiments of unilateral section of the spinal cord, observed an increase of the defensive phenomena on the opposite side—that is to say, in the anæsthetic limbs. Vulpian found the reverse results. The question cannot be definitely resolved. It seems to us, however, that the defensive phenomena are found in the great majority of subjects presenting any troubles of sensation, whether superficial or deep. They are more rare in individuals affected with spastic paralysis of the purely motor form, belonging to the clinical type of spasmodic tabes. In cases of total anæsthesia, such as found in total transverse sections of the dorsal cord (case noted by Dejerine and Levi-Valensi), those defensive reflexes are readily obtained.

Certain factors, still imperfectly known, should, nevertheless, have an influence on the intensity and evolution of those reflex phenomena. In conjunction with my intern, M. Rouillard, I have reported the case of a young man affected with Pott's disease, of acute evolution. From the fifth day, when the symptoms indicated but slight medullary compression (weakness of the legs, exaggeration of the tendon reflexes), we provoked defensive reflex movements in the lower limbs, from below a line corresponding to the sixth dorsal segment, while there was as yet no trouble of the objective sensibility. In the sequel we found the upper limit of the region in which the phenomena of defence could be provoked descend progressively till arrested at the foot; while, inversely, the domain of troubles of objective sensibility ascended gradually till it reached the level of the umbilicus.

In some cases of hemiplegia, I have seen the defensive phenomena (reflex hyperkinesis) diminish little by little in intensity, and disappear completely as the aggravation of the general symptoms indicated the extension of the lesions—a clinical fact common enough in hæmorrhages and softenings. I have noted the existence of those reflexes of defence in patients presenting the syndrome of intracranial hypertension. And it is common, too, to see them disappear as the pressure of the cephalo-rachidian fluid (measured by the manometer) gradually subsides. In one of my patients, who presented symptoms of serous accumulation in the cerebellar region, and displayed in the highest degree generalised defensive reflexes all over the limbs and trunk, those symptoms gradually disappeared with the progress of the cure which followed a decompressive operation of trepanning.

We cannot here insist on the value of the theories that have been advanced in explanation of the physiological mechanism of those movements, of which the most prominent characteristic is that of being completely removed from the influence of the will. Thus it is agreed that we admit having to deal here with a manifestation of medullary automatism. The reflectivity of the cord is exaggerated whenever its connections with the encephalon are rendered precarious or completely cut off. But, in order to explain the very special characteristics of the movements so generated, it must be admitted that the peripheral stimulation always calls into play centres of which the function is to produce movements that tend to secure the defence of the injured regions (Van Deen's "sensibility of reflexion"). It is the conception championed by Vulpian, and which appears to be the most satisfying; when we remember that, in the great majority of cases, those various involuntary movements of the upper or lower limbs are movements of flexion which tend to remove the region so irritated from the position of the stimulus, and to bring the limbs into contact with the body. This attitude of being rolled up—is it not that of the individual deprived of power to resist, who thus folds himself up? Thus is justified the use of the designation of *reflexes of defence*, by which those involuntary movements are now generally known. Pierre Marie and Foix, relying on the experiments of Sherrington and Philipson on a dog whose cervical cord had been divided (spinal dog), have proposed another explanation of those movements: they represent collectively a series of co-ordinate automatic complex actions, which "indicate the inhibition of some muscular groups and the stimulation of some others. They represent the spontaneous movements of liberated medullary automatism; and correspond to the more habitual expression of this automatism, the automatism of walking." This theory, brilliantly delineated, is very seductive; and, if demonstrable, would justify abolition of the term *reflexes of defence*—which has, indeed, so far as regards the retreating movement of the limb, been replaced by MM. Marie and Foix with that of the phenomenon of the abbreviators. But, as A. Thomas remarks, those flexion movements are often associated with those of adduction or abduction, which are no part of the mechanism of walking: they may be also elicited by stimuli originating in the viscera or mucous membranes, a fact which by no means accords with the hypothesis of a peripheral stimulus which solicits the limbs to a display of their walking function. Finally, what explanation would such view of the movements of the lower limbs give of those of the upper ones: forcible flexion of the hand on the forearm, and flexion of the forearm on the arm; with forcible pronation and slight abduction of the arm?

We are accordingly of the opinion that it is necessary only to consider that those involuntary or defensive movements are manifested in all cases in which, as the result of irritation or lesion of the pyramidal tract, the medullary centres are cut off from the integral influence of the brain; but it seems also necessary that there should exist, on the sensory section of the reflex arc, an alteration of some kind to facilitate the genesis of the phenomenon. It now remains for us to pass in review the nervous diseases in which examination of these reflexes may prove useful to the clinician either from the point of view of diagnosis or prognosis. The defensive reflexes have been noted in hemiplegia; but only in those cases in which the hemiplegia was originally incomplete, or in the transitory complete hemiplegias which are not the result of a destructive lesion dividing the fibres of the pyramidal tract. They are absent, even from the outset, when extensive foci of hæmorrhage or of cerebral softening have produced a more or less complete paralysis. They are observable, however, in cases in which focal lesions incompletely destructive, or juxta-pyramidal ones, occupy a position near the motor zone; which is, accordingly, merely compressed or œdematous. For the same reason, they belong to the symptomatology of paralysis resulting from cerebral or meningeal œdema: produced by ventricular distension, by meningitis, or by meningeal hæmorrhage. In a word, they have the characteristics of incomplete alterations of the pyramidal tract. In a later stage, after the period of repair, these defensive phenomena present themselves in certain spasmodic hemiplegias; but they have no longer the prognostic significance which they present in case of an individual struck down but a few hours before, and displaying a complete, but flabby paralysis; when their existence furnishes some grounds for the formulation of a favourable prognosis.

As already pointed out, the defensive reflexes form a part of the syndrome of intracranial hypertension. They are generalised then, and found in the upper limbs as well as lower. However, in the absence of signs of localisation, exaggeration of the reflexes of one side would favour a diagnosis of irritation of the pyramidal tract of that side. Their progressive and permanent disappearance after decompressive craniotomy would suggest a serious meningitis rather than a cerebral tumour, and thus contribute to a favourable prognosis. In the true forms of meningitis, which are always accompanied by considerable increase of the pressure of the cerebro-spinal fluid, the defensive reflexes are but slightly developed. They disappear with the onset of the terminal comatose period; on the other hand, in cases which proceed to recovery, they persist long during the convalescence.

In neoplastic lesions of the bulb and mesocephalon, it is possible to observe defensive reflexes, but it is more especially in cases of compression of the spinal cord, in transverse lesions, limited or diffuse (spinal syphilis, disseminated sclerosis), that we have noticed them in greatest frequency. They seem to be more rarely present in the combined scleroses, the lateral amyotrophic cases. They are absent in limited lesions of the grey matter of the cord, or of the posterior columns; and, *a fortiori*, in those of the nerve-roots. In those cases, the defensive phenomena express suppression, degeneration, or irritation of the pyramidal tract.

Thus we see that examination of the reflexes of defence—a precarious phenomenon—contemporary with the earliest symptoms of alteration of the pyramidal system, can give very valuable indications from the standpoints of diagnosis and prognosis; and we are able to understand that the presence of those signs, in addition to other characteristics derived from the study of the cutaneous and tendinous reflexes may be of great help in embarrassing cases.

Do those reflexes specially characterise certain forms of paraplegia? M. Babinsky, in discussing the features of one of the forms of paraplegia—paraplegia with flexion—has insisted on the importance of the reflexes of defence in this variety; in which failure and final disappearance of the tendon reflexes are observed. In a case published in 1909, and figured in our article in the *Précis de Pathologie générale*, Jean Camus and myself were equally struck by the intensity of the defensive reflexes; and that was one reason for cancelling the diagnosis of hysterical contracture, even in presence of the most characteristic symptoms of that neurosis. Since that date we have observed defensive reflexes in a great number of paraplegic cases, and it does not seem to us desirable to institute a distinction, from the standpoint of the *régime* of reflexes, between the paraplegias in which flexion predominates, or "cutaneo-reflex" (Babinsky), and those in which extension predominates, or "tendino-reflex."

The presence of defensive reflexes appears to be of the highest importance in the determination of the exact seat of a medullary lesion. Brown-Sequard and Vulpian had already insisted on the abolition of reflexes of every order, when the lesion had destroyed the lumbar enlargement of the cord. More recently, P. Marie and Foix have drawn attention to the localising value of a modification of the automatic medullary reflexes. Finally, Babinski and Jaworski have endeavoured to establish the following law: in cases of limited compression of the cord, the superior limit of the compression corresponds to the superior limit of the anæsthesia, while the inferior limit is indicated by the level at which the defensive reflexes cease to be obtainable; that is to say, for example, that if a tumour compresses the cord at the level of the second or third dorsal segment, the anæsthesia which involves the whole surface of the lower part of the body ends on the thoracic surface at a plane which corresponds to the second root-segment; while the defensive phenomena cannot be elicited by pinching of the skin, but below the plane corresponding to the third root-segment. If the space between the surface lines of limitation is of large dimensional area, there is reason for believing that there is compression over a considerable extent, such as is produced by pachymeningitis or extra-dural tumour. This opinion has, up to the present, been confirmed in one case only. In the anatomo-clinical fact which I described in conjunction with M. Rouillard, the seat of the very circumscribed tuberculoma did not correspond to these indications; as the zone of reflex phenomena of defence began to be developed above the actual seat of the tumour, and gradually descended. On the other hand, the data furnished by the upper limit of the anæsthesia permit a more exact localisation. It is true that, in tuberculous lesions, and indeed in those produced by other tumours, the phenomena of compression may be exaggerated by the presence of superadded meningo-medullary inflammatory complications, transgressing the limiting planes of the upper and lower extremities of the tumour. Thus we see that the diagnosis of the actual position and extent of medullary lesions will always be a matter of subtle delicacy; and it is well to know that, among the numerous suggestions deducible from the study of defensive reflexes, the sign proposed by MM. Babinski and Jaworski, if experience confirm its value, may become one of a certain degree of importance for the clinical observer.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by D. Souligoux, M.D., Surgeon to the Tenon Hospital, Paris. Subject: "The Treatment of Wounds of the Chest."*

THE Local Government Board has given its approval to the scheme for the establishment of a tuberculosis dispensary at the Brompton Hospital for Consumption in connection with the boroughs of Chelsea and Kensington. This is a tentative arrangement for six months.

ORIGINAL PAPERS.

PERIODS OF STRESS IN HUMAN DEVELOPMENT. (a)

By EUGENE S. TALBOT, M.D.,
Chicago, Illinois.

The embryonic history of man is essentially the same as that of the invertebrates as well as the lower vertebrates. The differentiation lies in the development of some structures and the sacrifice of others for the benefit of the organism as a whole. There is an economy of growth governing the relations of the organs to each other. Development of the organism involves changes in which certain parts cease to advance after certain periods, while others assume a relatively greater importance. Some of the functions, possessed at the beginning by certain cells, are lost and the cells develop in one direction only. While these changes fit the cells to perform their specific purposes in the organism, they create a loss of power and independent existence and are, in this respect, expressions of excessive or arrested development, either of which constitutes degeneration.

Certain organs, well developed in early life, undergo arrest of development, degenerate as the organism advances, cease to grow or disappear. The organism as a whole is limited in its period of growth, and having reached a certain stage ceases to increase in size and remains practically stationary throughout life. Growth of the organism is regulated by the activity of certain ductless glands, among them the pituitary gland. An organ may check or stimulate growth, but when it fails pathologic conditions result in the organism of excessive or arrested development.

In the process of man's development from the primitive cell, periods occur in which unfavourable influences act so as to occasion a stress or struggle. These are called periods of stress. A stress period is so-called because a new function disturbs the physiologic balance previously existing. Examples are the onset of menstruation in the girl and its disappearance in the woman. The stress may act on the organism as a whole or on a particular part, and if it is upon the organism the organs least able to bear it show its effects most clearly. Thus, partly developed organs, the functions of which are as yet imperfectly established, are likely to be checked entirely in their development or take abnormal courses. The organs of greatest importance may secure nourishment and nervous force at the expense of others, bringing to bear a struggle for existence among the different organs. If the stress falls on one part local changes may result in arrested or excessive development—namely, in degeneration of the particular organ. The changes will be more marked if the stress period occurs during the plastic state of the affected organ, yet under such conditions reparative changes are apt to be correspondingly active.

Degenerative Influences.

Three kinds of unfavourable influences affect the organism or its parts—the mechanic, toxic and nutritive.

Mechanic influences are frequently operative in the direction of the development of some organs. The weight of the body may operate in infants and produce deformities like bow-legs. Mechanic influences are often very effective in changing the shape of the jaws and teeth. An influence, ordinarily insufficient to produce an abnormality, may do so at a period when it is favoured by weakness of the organ from other causes.

The germs of disease may be inherited or the general nutrition of the fœtus may be checked in development so that the child inherits a tendency to disease. Through the check in the fœtal stage, the power of the white blood cells to devour fœtal structures is lost and the organs which should protect against disease by forming antitoxins fail to perform their functions. For this reason, in the degenerate, many infections and contagions assume their early destructive types. The influence of such checks in the parent is shown in the bony maldevelopment, illustrated in animals by Charrin and Gley, and in man by Coolidge. The facial bones, jaws, and teeth are often thus affected. While the effect of the disease upon the parent is only temporary, the development of the child may be hindered in its higher tendencies. Mothers have borne moral imbeciles, epileptics or lunatics after a pregnancy during which they were attacked by a contagious disease, and the children of previous or subsequent pregnancies were normal. The children of pregnancies previous to the one complicated by the contagious disease or toxic elements may be healthy, while those of subsequent pregnancies are defective. Any contagious or infectious disease may not interfere temporarily with bodily strength, but may produce a complete change in the parent's system even affecting the mental powers.

Nutritive influences, the most commonly noted, are manifested in two directions: either in an excess of nutrititive material, which, when the proper conditions are present, leads to excessive development of the affected parts, or in conditions unfavourable to nutrition, an arrested development occurs. These unfavourable conditions are, lack of nutritive material, lack of proper assimilation, and lack of proper nervous influences to stimulate and control nutrition.

The periods of stress occurring during development are called periods of evolution and those occurring during maturity are called periods of involution. Arrests or excesses occurring at any period during development underlie all so-called deformities of the body. There are often reversions in which the features of the adult fish, reptile, bird and mammal characteristic of the fœtal stages through which man passes, are reproduced. The structures most prone to such degenerations are the head, face, nose, jaws and teeth, since these features are still in process of evolution and they are peculiarly susceptible to the law of economy of growth in the struggle for existence among organs. This struggle among organs takes place in animals as well as in man. Wild animals in captivity, and others through domestication (change of environment and food), present evolution in structure similar to that of man. Structures undergoing degeneration are, because of greater or lessened blood supply, more liable to disease than those more highly evolved. Marked illustrations of this may be found in irregularities of the teeth out of harmony in jaw development where the teeth are not being lost fast enough for the receding jaws, in interstitial gingivitis, and in excesses and arrests of development of the structures of the nose and sinuses.

Struggles for existence on the part of the different organs and systems are most ardent during periods of evolution and involution. During development *in utero*, or during the first dentition, or during the second dentition (often as late as the thirteenth year), or during puberty and adolescence (fourteen to twenty-five), or during the climacteric (forty to sixty), when uterine involution occurs in women and prostatic involution in men, or finally during senility (about sixty and upwards), mental or physical defects may show, a congenital tendency to which has remained latent until this period of stress. When systemic balance, the rational attendant of evolution, is disturbed by a change in environment, the organs do not pursue their normal growth. Such disturbances are most apt to exist during periods of stress because of the varying relations of different organs.

The first intra-uterine period of stress occurs within the early third of embryonic life, when the embryo rapidly passes through the stages which correspond to the adult fish, reptile, bird, and mammal types and assumes the form of the human being. In this period are the most marked deformities and monstrosities which often result in the death of the fœtus. Such disturbances in development are likely to affect most powerfully the structures in which evolution is variable. Their influence must strongly affect nutrition of the dermal bone elements of the skull, face, nose, and jaws, and hence must affect the teeth, although the results are not always obvious until the later periods of stress.

(a) Paper read at the Section of Stomatology, International Congress of Medicine, London, July, 1913.

A check on or an excess of the growth of the higher organs of the nervous system frequently results in impairment of the mental faculties to the extent that any of the degenerations may occur. In these cases, the brain remains in the stage characteristic of the common simian ancestor, or the higher faculties may attain only the development of primitive races in whom emotional control and ethical ideas are insufficient to meet the exigencies of civilised states. Together with, and dependent on, this cerebral mal-development, are deformities of all the structures, including the head, face, nose, jaws, and teeth.

In the latter part of intra-uterine life, imperfect development of the nervous system may be accompanied by a premature growth of the teeth so that they erupt before or at birth. Prenatal or congenital teeth often accompany imperfect dvelopment of other organs. The intra-uterine development of man and ape is so similar that they congenitally resemble each other more closely than do the developed adults. The fœtus of the ape resembles an adult more than the adult ape resembles the adult man. In extra-uterine development a marked contrast exists. The ape passes through a short infancy to a condition from which there is no further development.

Periods of stress are furnished by the different periods of embryonic as well as by those of extra-uterine development. Even sex is determined by conditions of stress after a certain period. Poor maternal nutrition will determine an excess of males while good will determine an excess of females. Arrests at some periods of intra-uterine life will produce prematurely senile states, since there is a period of intra-uterine life wherein the fœtus wavers betreen the senile appearance of adult anthropoid apes and that of mankind in youth. This intra-uterine stress may be an expression of the general nervous exhaustion of the mother, which first affecting the check influences of the central nervous system, finally leads to unchecked excessive functioning on the part of the local nervous systems. In consequence, the mother is unable to manufacture proper elements of nutrition or to properly excrete waste material. The fœtus, therefore, starved and poisoned, fails to pass through the periods of stress in a complete, well-balanced manner. The stress acts most strongly on those structures which are transitory and variable in type. A strong influence may be exerted on the fœtus, mentally or otherwise, by stress in the mother. The human fœtus exhibits very decided reaction to sensory impressions of the mother.

The fœtal periods of stress in the human organism deserving most attention are those coming at sex differentiation and the senile or simian period of intra-uterine life, usually about four and one-half months after conception. Three conditions, infantilism, masculinism, and femininism, and occasionally a mixed state, result from arrest of development before, during, and after sex differentiation in intra-uterine life. As sex organs and sex nerves are differentiated before the sexual appetite appears, the mental side of sex can be determined only in extra-uterine life. The three conditions are practically all arrested development of the promise of the child type. As the female type most nearly approximates, from the view-point of bodily and nervous development, the promise of the child type, checks or excesses in its deveopment result in masculinism. In the first instance the female has proceeded so far in development as to have female organs and their functions while retaining traces of the lower male type. In another instance the male has proceeded along the line of evolution towards the female type, but before sex has been fully differentiated further development is checked and the male type is finally assumed as the predominant one. Both sexes proceed from an indifferent type, which resembles the hermaphroditic found in the lower animals. Arrest of development takes place at any point in the embryogeny. Arrest at periods of stress through any process which retards development, peculiarly influences the development of the child after birth. When due to syphilitic conditions, which exert a severe strain, the child readily succumbs to the infections and contagions. It also produces early senile stress in the child, so important as regards the head, face, nose, jaws and teeth. Forces exerted during the senile period of stress play a large part in determining precocity and its product, premature senility with osseous deformity and other consequences. Neurasthenia in the parent may result in bony arrest or excess of development such as is shown in macrocephalic and micro-cephalic heads. The head, facial bones, nose, jaws, and teeth are peculiarly affected by disease.

The power of passing through the fœtal periods of stress depends on the condition of the fœtal organs at the time of the periods of stress, and partly on inherited factors, and partly on maternal conditions. Defect in any of these conditions at this period of stress may so affect the struggle for existence that reversionary conditions gain the ascendancy. This is noted in cyclopia, in which the pineal body becomes an actual eye as in certain lizards, while the paired embryonic eyes in man disappear. Stress also at other periods causes arrested brain types in idiots at the stages resembling the brains of Sauropsidæ (bird and reptilian types).

Extra-uterine Periods of Stress.

During the entire developmental life of man, extending over the first thirty years, there are marked changes in the nervous system and associated organs. There is constant demand on the powers of nutrition. There are produced what may be called the post-natal periods of stress. The first period of infancy is comparatively uniform and extends to the eruption of the temporary teeth, which marks the beginning of the post-natal or second period of stress. During this period of infancy disturbances are seldom met with if the infant is properly protected. The food is introduced in a practically sterile condition from the mother's breast. In the absence of infections the respiratory and circulatory organs act normally, and growth is uninterrupted after the first normal decrease in weight. This second period of stress involves a series of changes which occupies the time from six months to two years after birth, and which are almost as remarkable as the changes occurring in the early weeks of intra-uterine gestation. At this time the digestive organs assume more complex functions; teeth prepare the solid food; the intestinal canal becomes accustomed to the presence of normal micro-organisms and prepared to resist the invasion of injurious germs; urination and defæcation become subject to voluntary control and restraints of decency; power to stand upright and to walk is attained; the faculty of speech is developed, and at this period deformities of the head, face, nose, jaws, and teeth are seen.

The second dentition, beginning with the sixth year, forms the third period of stress. At this time deformities of the head, face, nose, jaws, and teeth are more noticeable. The fourth period is ushered in by puberty, at which time the generative organs begin to be functionally active; marked changes are made in the brain and nervous system; the osseous system reaches its complete development at the close of adolescence, and the organism assumes a stable condition which it maintains without apparent change throughout adult life. The climacteric period, marked in women about the fifth decade and the failure of the sexual powers in man somewhat later, necessitates readjustments of metabolism of great importance to all organs, and notes the fifth period of stress.

Owing to the struggle for existence which occurs at puberty between the old type of the chondrocranium and its new type as supplemented by the dermal bones, the nervous system may take a distorted ply and arrest the physical and mental development so that body and face remain at the childish point; or the physical development may be checked, or the nervous system of certain organs may be checked while the body goes on to full development. Not infrequently the face is arrested at any period from birth to puberty. Hence many persons retain a youthful appearance throughout life.

The last period is that of decadence and senility, in which the unity or the organism is indicated, not by the preservation of all the organs in full vigour, but by the economy with which the failing resources are applied to the maintenance of vitally necessary organs to the detriment of those whose functions are less essential. In this period the teeth are liable to soften and to be lost as a result of interstitial gingivitis and are not replaced; the jaw atrophies and similar changes take place in other parts of the body. It is difficult to distinguish the effects of the failing nutritive powers from the effects of disease. If man were protected from the inroads of disease, which materially modify the natural process, he would degenerate and die in a different manner from the most commonly noted. Premature senility may evince itself in atheroma of the arteries at the periods of extra-uterine stress, an observation of which may be made in the children of vegetarians and in persons who have had fevers.

Since the importance of periods of stress in the development of the human fœtus has been pointed out, the greatest care and protection as well as careful study should be given to parent and child that degenerative influences may not lessen the chances of survival nor aid in furthering the degenerative tendencies of the human race.

CIRCUMCISION: THE ADVANTAGES OF A MODIFIED OPERATION. (a)

By THOMAS H. KELLOCK, M.D., M.C.Cantab., F.R.C.S.Eng.,

Surgeon to and Lecturer on Surgery at Middlesex Hospital, Surgeon to the Hospital for Sick Children, Great Ormond Street.

Mr. President and Gentlemen,—It may be that I should apologise for occupying your time with a subject that would seem to be of so little importance or interest as the operation of circumcision: it is such an ancient one, and so almost consecrated by antiquity, that to attack or criticise it may seem to savour of vandalism.

Still, sentiment and its antiquity should not excuse it if we feel that the mutilation of children by its performance is unnecessary or harmful.

It is not my intention to trace the history of the operation, or to attempt to unravel the mystery that surrounds its origin, but rather to inquire into the necessity for its very frequent performance in the present day, and to try and show that most, at any rate, of the advantages claimed for it may be attained by very much milder measures.

It is quite easy to say that a boy or man is none the worse for having been circumcised in infancy or childhood; but is this so, and are there no objections to the operation as generally performed, with complete removal of the prepuce and permanent exposure of the glans penis? The prepuce is the natural covering of the glans penis, protects it from irritation or injury, and preserves its sensory faculties. Denuded of this covering, the epithelium covering the glans becomes hard and less sensitive, and, although procreative power would not seem to be lessened, I think it is certain that the natural desire is modified, and ceases at an earlier age than in the case of the uncircumcised.

This is, perhaps, not the place to discuss the dangers of the actual operation, but everyone will allow that such do exist, and the roll of children who have lost their lives or suffered severely from the operation must be a long one. Sepsis, hæmorrhage, and such like have been answerable for a large number of what may almost be termed unnecessary deaths; whilst hæmophilia has frequently been brought to light, as it were, by this the first surgical experience of the infant. I would not contend that these dangers are very great ones, or that they are altogether absent from the milder operation I advocate; still they are present, and weigh against the performance of any operation unless it be really necessary.

Of all the conditions for which circumcision is advised probably the most frequent is difficulty of micturition, pain during the act, and all the ills which rightly or wrongly have been attributed to the dysuria. In such cases I believe circumcision is quite unnecessary. The difficulty in micturition is very often caused by a partial blocking of the urinary meatus by preputial adhesions immediately round it. The prepuce is normally adherent to the glans penis, and there is no reason why under ordinary circumstances it should not be allowed to remain so. If the closeness of the adhesion to the orifice of the urethra partially blocks this it can quite easily be separated just around it, and the dysuria, if caused in this way, relieved.

What I think is far more frequently a real cause of dysuria is a small pin-hole orifice to the urethra, which is often present when phimosis exists. I find quite a number of boys sent into hospital on account of inguinal hernia who have this condition. They have almost invariably been circumcised, but the pin-hole meatus, which is sometimes not large enough to admit a probe, has been left untouched. The remedying of this is a very simple matter, and is, I think, a point that should always be attended to at the time of the circumcision if this be done, or instead of it. Where, as is often the case when the prepuce is much adherent, the preputial orifice is small and will not allow easy retraction, and the prepuce is not unduly long, circumcision is not thereby rendered necessary, for a small incision on the dorsum and one suture is all that is necessary to allow of quite easy retraction.

When inflammation or suppuration occur under the prepuce it is a very common practice to perform circumcision; but here, again, all that is really necessary, provided the prepuce is not unduly long, is a small incision on the dorsum. These dorsal incisions for tight prepuce are often made much too freely, so much so that the slit prepuce hangs down on either side in unsightly folds; all that is usually required is one about a quarter of an inch in length, including, of course, both skin and mucous membrane.

If the conditions I have mentioned be complicated by an unduly long prepuce, or if the latter exist alone, it is often necessary to remove some of it before the other conditions can be properly dealt with; and it is here that I would advocate an operation considerably modified from that generally performed.

A very long prepuce may be said to be abnormal, but there would seem to be no reason why, in attempting to remedy it, we should go to the other extreme and create an abnormality in the other direction. Our object should be rather to convert the abnormal prepuce into a normal one—one that will come forward over the glans penis and protect it.

There would seem to have been some difficulty in obtaining this result, and it is generally supposed that if it be attempted cicatricial contraction will take place round the new orifice, and the last state of the child be worse than the first. It is, however, quite a simple matter if we only get away from the idea that the mucous membrane must be cut or trimmed off close to its attachment to the corona. Of course, if this be done, there is no possibility of the prepuce ever being able to come forward over the glans.

(a) Paper read at the Medical Society of London, December 8th, 1913.

The operation I advocate consists in the removal of only that portion of the prepuce that is redundant. After separating any adhesions there may be round the urethral opening, the prepuce that projects beyond the tip of the glans penis is cut off in slightly slanting direction parallel with the line of the corona; both the skin and mucous membrane are divided at the same level, and no more of the latter than of the former is removed. Then a small incision, including both skin and mucous membrane, about an eighth of an inch long, is made on the dorsum, which converts the round opening into a slightly pear-shaped one. The hæmorrhage is generally insignificant, and seldom calls for the use of artery forceps. In quite young babies this is all that is needed; in older children I generally put in four horsehair sutures. uniting the cut edges of skin and mucous membrane, tying them very tightly so that they drop out by themselves after four or five days, so obviating the necessity of their removal, which is a performance painful to the child and irritating to the mother or nurse. If the patient be under an anæsthetic, a little tincture of iodine may be painted over the wound, but no application or dressing at all seems as good treatment as any. The dressing of a circumcision is as unnecessary as it is painful to the child; they do much better without any. A small apron of gutta-percha tissue will prevent the diaper sticking to the wound, and more rapid healing takes place in this way than with any form of dressing.

The prepuce left in this way should be sufficient to just cover over the glans penis and leave the urethral orifice visible. It can be retracted once a day by the nurse for a week or so, and a drop or two of oil or a little soft vaseline placed on the glans will prevent it becoming sufficiently adherent to the prepuce to make retraction painful.

[I have been using the term mucous membrane to indicate the soft skin which lines the inside of the prepuce. Although, of course, it is an erroneous one, yet it is in common use, and serves a very useful purpose in a description of any operation to distinguish it from the skin covering the outside.]

There are other reasons given for performing the operation. Circumcision is said to prevent the infection with venereal diseases later in life, and there is no doubt but that the incidence of hard and soft chancres is less common in the circumcised than in the uncircumcised. It is quite obvious that the man who has a long prepuce that retracts with difficulty is liable during coitus to sustain cracks or fissures into which any virus may enter, a danger to which the circumcised, with a hard glans penis and no prepuce, is not so much exposed; and, if the sole object of the operation were the prevention of these diseases, it must be allowed that the complete operation is good and answers the purpose. But is the operation often done with only this object; and is not the man who has a short prepuce almost, if not quite, as safe when exposed to infection as one completely circumcised?

Gonorrhœa I need hardly mention, for it is quite obvious that an urethral infection by the organisms of this disease is equally likely to occur whether a man has been circumcised or no. Circumcision is often performed in the hope that it will cure the habit of masturbation. I do not suppose one should say prevent the habit, for it is doubtful if it is ever done with that object. For a time immediately after the operation the tenderness of the part naturally puts a stop to the habit, and this tenderness is equally produced by the milder operation; but whether this result is a lasting one is, I think, doubtful. I cannot claim to have had to deal with any large number of these cases, but I think the habit is almost as common amongst those who have been circumcised in infancy as in the uncircumcised, and so I do not think it can be claimed that either operation cures it. On the contrary, it is easy to suppose that the constant irritation of the clothes about an exposed glans penis might well originate it.

Mere sentiment on the part of the father is often a reason why babies are circumcised. One often hears a man say, "I have had every one of my boys circumcised," but will give no better reason than that he thinks they will be the better for it "later on." This is really no valid reason why the children should be unnecessarily mutilated, and generally means that the father has suffered from some venereal disease; and, if the real reason is his anxiety to protect the children from the same, the question is reduced to the one I have just mentioned—the prevention of venereal disease by the operation.

I am happy to say that one now meets with quite a number of boys for whom, by various surgeons, this modified operation has been performed with excellent results, and I hope to see it almost, if not completely, take the place of the old operation; and I shall be happy if what I have now said may convince any advocate of the old operation that equally good results may be obtained by the milder and more humane one.

RECENT WORK ON THE ÆTIOLOGY OF GALL-STONES. (*a*)

By J. W. McNee, M.B., Ch.B.,
Extra Hon. Physician, Royal Hospital for Sick Children, Glasgow.

STATISTICS show that at least 10 per cent. of all adults are carriers of gall-stones. As to the influence of age and sex in their causation, Schwartz reported that out of 146 patients who had required treatment for cholelithiasis 69 per cent. were females and 31 per cent. males, the great majority of the former being between the ages of 20 and 40 years—*i.e.*, in the period of child-bearing: while Schroeder showed that in females who had borne children the figures were ten times greater than in those who had not.

The views of the ætiology of gall-stones which have been held for the last twenty years are those of Naunyn, who recognised two factors in the formation of all varieties of gall-stones, (1) stasis of the bile in the gall-bladder, and (2) inflammatory catarrh of the gall-bladder mucosa induced by micro-organisms. Naunyn held that in a condition of stasis in the gall-bladder the epithelial cells, dying as the result of inflammation of the gall-bladder, were shed off, and that the inspissated bile extracted the cholesterin from them for the building up of stones. The work of Aschoff and his pupils, now accepted practically throughout Germany, has shown that these views are incorrect. According to Aschoff, cholesterin is secreted by the liver itself, and the droplets of cholesterin found in the cells of the mucosa are simply absorbed secondarily from the inspissated bile. In the formation of gall-stones stasis is a most important factor, in that it permits the separating out of the constituents of gall-stones from the bile, and in two conditions in which the proclivity to gall-stone formation is well recognised—viz., the

---

(*a*) Full abstract of paper read before the Glasgow Medico-Chirurgical Society, November 28th, 1913.

pregnant state and general adiposity, there is likely to be considerable and continuous pressure on the gall-bladder, with stasis as the result. A second factor is the altered concentration of the constituents of the bile—*i.e.*, increase of the stone-forming elements. It is now known that the amount of cholesterin in the blood-serum is increased above the normal during pregnancy, especially in the later months, and in certain conditions of disease—*e.g.*, diabetes mellitus, arteriosclerosis, chronic Bright's disease, and many forms of jaundice; while the amount is below the normal in tuberculosis, tumours, and in all the acute fevers except enteric. By the Windaus digitonin method the normal amount of cholesterin in the bile has been ascertained to be about 1.5 to 1.7 grms. per litre; but the speaker, working in Aschoff's laboratory, found, in four cases of pregnancy which came to *post-mortem*, figures of 6.88, 7.20, 6.60 and 6.37 grms. per litre respectively, and in the case of a patient who died of acute phthisis within a month or two after delivery a figure of 12.5 grms. per litre.

Alteration in the amount of the pigment is of little consequence, but increase in the lime salts is of great importance. The third factor in the formation of gall-stones is infection by micro-organisms, most commonly of the typhoid-coli group. When this occurs the lime salts in the bile are increased partly from the serous exudate which exudes from the inflamed wall, and partly because in a chronically inflamed gall-bladder there is great new development of mucous glands, from which salts, chiefly carbonates of lime, are secreted with the mucin. Aschoff's work, however, has shown that there is a class of gall-stones, including about 20 per cent. of all stones, which have, at first, at least no inflammatory factor in their origin. These are the pure cholesterin stones, which occur always singly and in a gall-bladder whose contents are, as a rule, sterile. This stone arises by the separating out of cholesterin in a gall-bladder in which, in addition to the presence of considerable stasis, there is an excess of cholesterin in the bile. In section it is seen to be crystalline, the crystals being arranged somewhat irregularity in the centre and radiating out on all sides. It develops, as a rule, quite without clinical symptoms, and is often accidentally seen at *post-mortem.* If, further, the common bile duct becomes partly obstructed—*e.g.*, by a solitary cholesterin stone tending to block the neck of the gall-bladder, organisms readily pass up from the bowel and set up an inflammatory cholecystitis. When this occurs the character of the bile is immediately altered, lime salts being present in excess, and the cholesterin stone becomes coated with a mantle of chalk and cholesterin, darker in colour than the pure cholesterin, and deposited in concentric layers. Thus is formed the "combination-stone." The commonest type of stone is the facetted cholesterin-chalk, or cholesterin-chalk-pigment stone, which is always multiple and may be found in extraordinary numbers. These may arise either in a gall-bladder which has become infected with organisms and which contained no previous stone, or they may be formed in a gall-bladder where a stone of aseptic origin existed before the onset of inflammation. These stones are built up concentrically from the very centre and have no radiate structure. In 130 cases collected from *post-mortems* in his own laboratory Aschoff found in 6 per cent. pure cholesterin stones; in 20 per cent. combination stones (with or without other stones); in 63 per cent., multiple cholesterin-pigment-chalk stones, without any combination stone; in 10 per cent., other stones of varying kinds, including pigment-chalk stones, etc. Thus few cases of pure cholesterin stones are not followed subsequently by inflammatory changes; while 20 per cent. of all cases of inflammatory cholelithiasis pass through a non-inflammatory period.

It should be recognised that the presence of a gall-stone or of gall-stones is the symptom of a disease, not the disease *per se.* For the presence of a stone of aseptic origin the abnormal element lies in the composition of the bile; in the case of stones of inflammatory origin the pathological condition is the cholecystitis or catarrh of the gall-bladder. Therefore, any treatment, to be truly rational, must not only aim at removal of the gall-stones present, but must combat the stasis in the bladder by adequate drainage, must promote healing of the inflamed and often ulcerated gall-bladder wall, and must take cognisance of the conditions which tend to increase the excretion of cholesterin in the bile.

OPERATING THEATRES.

HAMPSTEAD HOSPITAL.

Three Cases of Colectomy.—Mr. Jackson Clarke operated on two cases in which he did partial colectomy with end-in-side implantation of the divided ileum into the pelvic colon.

Case 1.—A woman, æt. 24. She had had appendix removed, but this was followed by local pain. The abdomen was re-opened and one broad, dense adhesion divided and sewn over. The patient was better for a time, but the pain returned. She was re-admitted, and very extensive adhesions were found all over the ascending colon. The latter, with half the transverse colon, was removed, and the ileum implanted into the upper part of the iliac colon. The patient recovered without a bad symptom, being out of bed on the 15th day.

Case 2.—A woman, who gave a history of years of abdominal pain. In June, 1911, she had had appendix out at St. Thomas's. At a first operation at Hampstead Hospital on July 17th, 1913, right nephropexy was done and removal of a thyroid adenoma. There was no relief of the pain. The second operation was on August 6th, 1913. Many adhesions were found; one held the stomach close to right iliac fossa. The cæcum and ascending colon were also covered with adhesions and some large caseous glands were seen in the mesentery; the latter were removed, together with the same parts as in Case 1. There was much shock and some vomiting, which last was most likely due to denudation of the third part of the duodenum. The patient made a good recovery.

Case 3.—This was that of a female, æt. 25, with the following history: Six days' pain in right iliac fossa; nausea; no vomiting; bowels costive. The patient had had three previous attacks, two about five years before and one a month previously. On examination, there was good movement; no distension; tenderness, resistance and a small mass in right iliac fossa; temperature, 100.2°; pulse, 100. At the operation, which was performed on admission (C.E.—ether), Battle's incision was made. The appendix, which was lengthy and had thickened walls, was found to be bound down by a large number of old, dense adhesions to coils of small intestine; removal was done, and the adhesions ligatured and removed. Rectal saline with sanatogen were given. The wound healed by first intention. The patient complained of pain in right iliac fossa on 16th day, and again, with vomiting, on 19th day. Great trouble was experienced in opening the bowels. Patient was discharged January 17th, 1913. She was readmitted on February 17th, 1913, with a history of 14 days' continuous pain in right iliac fossa; vomiting on two or three occasions; marked constipation. There was tenderness all over right iliac fossa; no distension, rigidity or mass. Temperature, 99°; pulse, 88. At the operation on February 19th (C.E.—ether) a median subumbilical incision was made. The upper part of the small intestine was found slightly distended. A long, thick and very tough adhesion, two and a half inches in width, was found passing from the outer side of the cæcum to the peritoneal aspect of the scar. A large number of small adhesions were found. The adhesions were ligatured and excised. Rectal saline was given. There was a small patch of pleurisy in the left side of chest. The patient complained of pain in right iliac fossa after third day. The wound healed by first intention. Patient refused operation for short-circuiting, and still complained of some pain on discharge on March 15th, 1913.

Mr. Jackson commented on the large number of cases of appendicectomy in which adhesions formed after the operation.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

MEETING HELD FRIDAY, DECEMBER 12TH, 1913.

The President, MR. CHARTERS J. SYMONDS, in the Chair.

EXHIBITION OF CLINICAL CASES.

DR. F. PARKES WEBER showed a case of chronic myelocytic leukæmia treated by benzol, etc. The patient, æt. 59, was admitted to hospital under Dr Parkes Weber in August, 1913. The spleen was hard and greatly enlarged, bulging forward and reaching downwards into the pelvis. The liver was also enlarged, the lower edge being three finger-breadths below the costal margin in the right nipple-line. The superficial lymphatic glands appeared unaffected, excepting for slight swelling of those in the groins. The blood-picture was typical of myelocytic leukæmia. The teeth and gums were in an unhealthy condition. The stomach contents after a test-breakfast were found to contain no free hydrochloric acid. In the hospital the patient did not seem acutely ill, though he was weak. Brachial systolic blood-pressure, 110 mm. Hg. Dr. R. Gruber made an ophthalmoscopic examination and reported that the fundi were normal. The Wassermann reaction for syphilis and Pirquet's anti-reaction for tuberculosis were both negative. There was often slight evening pyrexia (about 100° F.) in the hospital until September 29th, but since then there had been none. As he had already been treated by Röntgen rays in another hospital, it was decided to make a trial of benzol-therapy, introduced by A. von Korányi and G. Kiralyfi, of Budapest, in 1912. In the present case gelatine capsules were employed, each containing a mixture of 0.5 grm. benzol and 0.5 grm. pure olive oil. In this form the patient was given 0.5 grm benzol three times daily from August 15th to August 23rd; from August 23rd to September 2nd the same dose five times daily; from September 2nd to September 16th 1 grm. three times daily; from September 16th to October 20th 1 grm. four times daily. The benzol treatment was then discontinued, as it had led neither to decided objective nor to subjective improvement, and Röntgen-ray treatment under Dr. Jas. Metcalfe was immediately commenced. Since then the spleen had obviously greatly diminished in bulk and the quality of the blood had improved. On August 14th (before the commencement of the benzol-therapy) the blood-examination gave: Red cells, 3,400,000 in the cubic millimetre of blood; white cells, 130,000 (of which the polymorphonuclear neutrophiles constituted 45.2 per cent., and the myelocytes and myeoblasts 29.9 per cent.). On October 20th (when the benzol-therapy was discontinued) the blood examination gave: Red cells, 2,532,000; white cells, 219,000 of which the polymorphonuclear neutrophiles constituted 57.14 per cent., and the myelocytes and myeloblasts 25 per cent.). On December 2nd the blood examination gave: Red cells, 5,350,000; white cells, 76,200 (of which the polymorphonuclear neutrophiles constituted 55 per cent., and the myelocytes and myeloblasts 31 per cent. In addition to the treatment mentioned above, the patient, on August 25th, was given (by intramuscular injection) 20 c.c. of fresh defibrinated blood from a healthy man, but this had no obvious therapeutic effect of any kind.

MR. ARTHUR EVANS showed a case of suppression of urine in a boy, æt. 11, after operation for acute appendicitis, cured by double nephrotomy. The boy was admitted into hospital at 10 p.m. one day in August, 1913, and was operated upon on the same night for acute appendicitis. The tip of the appendix was acutely inflamed and contained pus, which, as the appendix was being delivered through the wound, burst through the appendix wall and was caught upon a gauze pad; the pus did not foul the peritoneal cavity. There was a little free fluid in the peritoneal cavity; a rubber drainage tube was inserted in the wound and reached to the site of the appendix; the rest of the wound was sewn up. As soon as the patient returned to the ward saline solution was administered per rectum. The next day the boy was sick twice. During the twenty-four hours eight pints of saline solution were given. On the third day ten pints of saline solution were given per rectum. No fresh abdominal signs manifested themselves; the drainage tube was removed and a gauze plug inserted. The patient had by this time received 2 gr. of calomel in ½-gr. doses, and the bowels were moved twice. On the fourth day the patient was quite comfortable and his bowels were moved twice; the temperature reached 100° F. in the middle of the day, the pulse was 86, and the respiration 34; in fact, the condition was perfectly satisfactory. On the fifth day, at 2 a.m., the patient complained of pain in the left loin and vomited three times. He was given three minims of oil of cajuput at 2 a.m. and one minim of tincture of iodine at 4 a.m. The pain became easier later in the morning. The feeds given consisted of lemonade, and milk with barley water; the boy was sick after each feed. At 11 a.m. the patient passed about 3 dr. of urine deeply stained with blood (the deposit obtained by centrifugalising showed blood and bacteria, both bacilli and streptococci; there were no casts.) On the sixth day the patient still had some pain, and it was now in both loins. His colour was not good and the pulse was weak. No urine had been passed since 11 a.m. the previous day, but now about 2 dr. were voided, looking like undiluted blood. This on being centrifugalised showed blood, pus, black pigment granules, oxalates, and a few large cocci; there were no casts. Hot fomentations to the loins had been continued since the day before. At 5 p.m. a hot pack was given, as vomiting was persistent. The boy seemed more comfortable until 7.30 p.m., when he had a convulsion, the face twitching and the eyes fixed; two pints of citric acid solution were given per rectum. At 8 p.m. the boy was unconscious and the pulse feeble: three pints of saline solution were given intravenously and two pints per rectum. A hot-air bath was given. The skin did not become moist. At 8.45 p.m. the pulse was only just perceptible. At 9.20 p.m. the patient was taken to the operating theatre, and Mr. Evans rapidly exposed both kidneys and freely laid them open, cutting through the substance of the kidney and exploring the pelvis in each case; no stone could be felt in either. Each kidney seemed much larger than normal, particularly the left, and each felt tenser than normal. From the left kidney he excised a small piece for microscopical purposes. Both kidneys bled profusely and both were plugged with gauze packing. As far as the gush of blood from the cut kidney would allow of an opinion, there was no urine in either pelvis. The patient was taken back to the ward, and at 9.45 p.m. 10 minims of brandy were given hypodermically and two pints of saline solution administered subcutaneously. The next day, at 12.15 a.m., the voluminous dressings had become sodden and needed packing; it was evident that urine as well as blood had soaked these first dressings. So profusely did fluid discharge from the kidney incisions that fresh packings were frequently necessary. The bladder was washed out at 11 a.m. The pulse was much stronger and the patient was quite comfortable; he did not vomit and there was no further convulsion. The patient made an uninterrupted recovery. Dr. R. G. Hebb, who had examined the portion of kidney removed at the time of the operation, reported that it was in a condition of "cloudy swelling." The urine had become normal, hence one might assume that the urine was normal before the attack of appendicitis, and so it was clear that in this case he had been dealing with an almost fatal attack of suppression of urine in a patient whose kidneys were previously normal.

Mr. T. H. **Kellock** showed four cases of malignant disease after treatment with radium. (1) A man, æt. 66, who was admitted to hospital in July, 1913. Six weeks previously he had first noticed an ulcer on the upper lip, caused, he thought, by a cigarette paper sticking to it; this had gradually increased in size, but had not caused him much pain. On admission the greater part of the upper lip was the seat of a hard-edged, rather deep ulcer, extending almost from one angle of the mouth to the other and into the mucous membrane nearly to the junction of the lip and alveolar margin of the jaw. Its hard, everted edge was clearly seen on the outside of the lip. There were no palpably enlarged lymphatic glands. The tongue was in a mild condition of chronic superficial glossitis. Five days later a radium tube containing 82 mgr. of radium was inserted into the lip from the end of the growth, the inside of the lip and gum being protected by a thin lead plate 2 mm. thick, fixed in position by attachment to the teeth. The radium tube was left in for 24 hours. Marked inflammatory reaction followed, and a typical radium necrosis occurred on the lower lip; all the hair on the upper lip fell out. Nothing further was done until October, when it was found that almost the whole of the growth had disappeared, leaving, however, a hard ulcer on the inner aspect of the lip towards the left side, and some induration around it. The ulcer was about ½ in. in diameter and very superficial. On this day a tube containing 82 mgr. of radium was again inserted into this part and left in for 18 hours. Inflammatory reaction was again marked, and a superficial ulcer appeared on the outer side of the upper lip. This took about a fortnight to heal, and at the end of that time the ulcer on the inside of the lip had disappeared. The condition showed still a little hardening towards the left side and a certain amount of scarring of the whole lip, but there was no ulceration, and the movements of the lip seemed very little impaired. Microscopical examination: Squamous-celled carcinoma.

(2) A man, æt. 35, who had first noticed that his throat was sore and that he had a swelling in the neck in January, 1913. In June, 1913, he attended a hospital, where a piece of growth was removed from the back of the tongue for examination. In the same month he was an in-patient at another hospital, where the growth was considered to be malignant and inoperable. He was admitted under Mr. Kellock's care in July, 1913, with a growth about the size of a walnut towards the left side of the back of the tongue, deeply ulcerated on the surface with hard edges. The mass was in contact with the soft palate and appeared to infiltrate the glosso-epiglottic fold on the left side. The movements of the tongue were impaired, and there was a good deal of difficulty in swallowing. The cervical lymphatic glands on the left side were markedly enlarged, they were very hard and only slightly movable; one enlarged gland could be felt on the right side of the neck opposite the angle of the lower jaw. A week later, under an anæsthetic, 82 mgr. of radium were inserted into the base of the growth and left for 15 hours. After a few days inflammatory reaction followed, the soft palate and base of tongue being covered with a yellowish membrane. After a week a marked diminution in the size of the growth was noticed, and this continued until it had practically disappeared in 14 days, and at the same time the glands in the neck became markedly smaller and more movable. The patient himself was quite sure that the circumference of the neck became much less. The reaction in the mouth had disappeared in 21 days. At the end of September the patient was readmitted; there was then practically no sign of the growth in the tongue, but the cervical glands were still considerably enlarged. These were removed by operation, the whole of the chain on the left side and one gland on the right side being excised. The wounds healed by first intention, and the patient was discharged. When shown there was nothing to be seen or felt of the growth on the tongue, and the neck on the left side felt clear; there was, however, a little hardness about the scar on the right side of the neck.

(3) A woman, æt. 50. The patient stated that she had had a thin yellow discharge from the right ear for two years, but had had no pain until August of the present year, when a tumour began to grow at the meatus; then the discharge became less, but was stained with blood. She had only been deaf since the appearance of the growth. For about a fortnight before admission to the hospital she had noticed that the right side of the face was weak. On admission a hard growth, about the size of a filbert, was found to be growing from the margin of the meatus of the right ear, involving the pinna and the skin in front of the ear. The surface was slightly ulcerated, and there was a foul-smelling discharge. There was no marked enlargement of the cervical lymphatic glands. The facial nerve on the right side was completely paralysed. Three tubes of radium, containing altogether 144 mgr., were inserted into the growth, and left in for 24 hours. The inflammatory reaction was not very marked. About a month later she was readmitted, and it was then found that most of the mass of growth had disappeared, and in its place a small slough was visible at the upper part of the meatus, surrounded by an ulcerated surface from which there was a slight discharge. Radium was again inserted in two tubes containing altogether 104 mgr. for 24 hours. Inflammatory reaction was absent up to the time of her leaving the hospital, and she had not been seen since. Microscopical examination: Squamous-celled carcinoma.

(4) A man, aged 55, had been in the habit of smoking a clay pipe. About a year ago he first noticed that he had a sore on the lower lip, but did not consult a doctor about it until November this year. On admission to hospital there was a typical malignant ulcer of the lower lip, situated a little towards the right side. The ulcer measured 1⅛ in. in length by ⅝ in. in breadth, the edges were very hard and there was slight discharge from the surface; the surrounding parts were not much affected but were covered with a thick brown crust. No enlargement of lymphatic glands was observed. Under local anæsthesia, a tube containing 82 mgr. of radium was inserted into the lip under the growth, the upper lip being protected by a thin sheet of lead. The tube was left in position for 21 hours. Inflammatory reaction followed almost immediately. The condition 15 days after insertion of the radium showed that the greater part of the growth had disappeared, the lips still showed signs of this inflammatory reaction, being swollen and slightly ulcerated, so that there was little difference to be observed between the original situation of the growth and the rest of the lip. On the inside of the lip there was a marked condition of radium necrosis, the surface being covered by the usual yellowish membrane.

Dr. F. S. **Palmer** showed a case of congenital heart disease and hemiplegia. The patient, a woman, æt. 22, had always been blue as long as she could remember, and suffered from shortness of breath on the least exertion, but she went to school in the usual way, and no special care seemed to have been taken of her as regards the heart trouble. She had had scarlatina at the age of six and attacks of acute rheumatism at 17 and again at 19 years of age. In March 1912, she had an attack of hemiplegia of sudden onset on the left side, involving the facial muscles. She was aphasic for a fortnight and then recovered her speech. Before the hemiplegia she was left-handed, but she now used both hands equally well. After her admission to the hospital she had such alarming syncopal attacks and cardiac dyspnœa that it was necessary to keep her in the recumbent position for nearly two months. Under treatment she had steadily improved in health, but she still walked with a slight limp, and there was some weakness of grasp in the left side. The points of interest in the case at present appeared to be as follows:—(1) The degree of cyanosis, probably from birth, with remarkable clubbing of the fingers and toes and polycythæmia. (2) The cardiac impulse could be felt best during active respiration about the sixth intercostal space in the anterior axillary line. Percussion and skiagrams showed no enlargement of the heart to the right, but the organ was generally increased in size and apparently lay with its long axis on the diaphragm. A loud, harsh murmur could be heard with its maximum intensity at about the junction of the third left costal cartilage with the sternum, and occupied the whole period between the first and second sounds, ending sharply with the latter. The murmur was well heard over the sternum in that position, but it was not audible over the whole of the cardiac area, nor was it conducted up into the back. Nothing could be heard at the back, and there was no evidence of any pulmonary complication. The absence of any other physical signs in the heart and large thoracic arteries pointed to some kind of congenital malformation with possibly superadded rheumatic endocarditis, or endo-pericarditis, as an explanation of the apparent hypertrophy of the left ventricle. (3) The hemiplegic symptoms had to a great extent disappeared. She used her left hand, and wrote unusually well with it. Her deep reflexes were equal but slightly increased, and the plantar response was flexor on both sides.

Mr. W. G. Spencer showed a case of latent fracture of the patella. The patient, a man, æt. 45 was exhibited six months after the union by wire of a transverse fracture of the left patella, along with photographs taken after the fracture, and after the union. He sustained a sub-aponeurotic fracture from slight violence, after which he was able to walk 9 miles and again 15 miles, also to go up and down stairs frequently until a week after the fracture, when, in stepping down one step, the aponeurosis tore widely, with separation of the fragments.

Dr. F. J. Poynton showed a case of cleido-craniodysostosis, with signs pointing to pressure on the brachial plexus by the rudimentary clavicles. It was that of a girl, æt. 19. Both clavicles had never been properly formed. The fontanelles were very late in closing (about the age of 17). There was no family history of importance, except that the mother had myxœdema about the time the girl was born. For the last five weeks the patient had had shooting pain in the inner side of the arm and the front of the chest and the right side; these had been getting worse. The teeth of the upper jaw were very irregular and ill-formed. Both clavicles were imperfectly ossified, each being in two pieces. The right arm showed a diminution in pulse when the shoulder was depressed, and there were areas of hyperæsthesia on the inner side of the arm and the front of the chest. The main point was the question of the pain and the appropriate treatment.

Mr. T. B. Layton showed a case of swelling of the upper jaw. The boy, æt. 18, had noticed the swelling on his face for two months. The teeth were all present with the exception of the third molars, and as none of these were milk teeth no unerupted teeth were likely to be present in the front of the jaw. Mr. J. S. Cocks had examined them with the hot and cold tests and found them to be alive, nor could he find any evidence of caries, but reported that there was an acute inflammation of the pulp of the left lateral incisor. On transillumination the right side was opaque, the left side was markedly translucent. On the left side there was a swelling of the maxilla, which bulged on to the face, the anterior two-thirds of the palate, and the inferior meatus of the nose. Externally it was oval and passed up to the lower mesial quadrant of the orbital margin, but above this the nasal process was felt to be of its normal shape. In the mouth the swelling did not cross the mid-line; the alveolar margin was expanded and not thickened; at the reflection of the mucous membrane from gum to cheek, in the space between the second premolar and first molar, was a circular area of ¼ in. diameter where there was no osseous tissue in the wall of the lump. Above and behind this the zygomatic process of the maxilla could be felt. The crowns of the lateral incisor, the canine and both premolars were rotated inwards.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

MEETING HELD DECEMBER 4TH, 1913.

The President, Dr. W. S. A. Griffith, in the Chair.

The following specimens were shown:—Mr. Alban Doran: An Occluded Vagina after Total Hysterectomy. Mr. J. D. Malcolm: Sloughing Fibroid with Complete Inversion of the Uterus. Dr. G. G. Alderson: Chrobak's Instrument for Embryotomy. Dr. Wilberforce Smith: Epidiascope Demonstration of Altmann's Granules in Tissues at point of Invasion by Squamous Carcimona of the Uterus. Mr. Gordon Luker: Hydatidiform Mole and Normal Ovum in Twin Pregnancy.

A Case of Primary Causes of Bartholin's Gland.—Dr. Herbert Spencer read notes of a case of primary carcimona of Bartholin's gland which he had removed, with the superficial inguinal (carcinomatous) glands, on March 3rd, 1912, the patient being well and free from recurrence on October 21st, 1913. A section through the growth and duct (which was unaffected) showed it to be an adeno-carcinoma with degeneration of the cells, causing it to resemble squamous carcinoma. Of the fourteen cases of which an abstract was given, only one other had remained free from recurrence. The disease was very rare, occurred at ages between 28 and 91, half the cases being over 50. The two sides were affected with equal frequency. The relation of the disease to gonorrhœa and inflammation was discussed and a short clinical history of the disease was given.

It appeared first as a small, hard, tender lump, accompanied by pain of a severe, lancinating character, sometimes passing to the coccyx and groin, and greatly increased by walking, menstruation, and coitus. The skin over it might be bluish and the remains of the hymen œdematous. The lump was much harder than an inflamed gland, and its surface was sightly nodular After a time the growth became apparent to the sight and burst through the skin at one or more orifices. The tumour might then become papillary or irregular or ulcerated on the surface and might be fixed to the pubic bone. The inguinal glands were early affected.

Remarks were made on the above by Dr. Eden, Dr. Russell Andrews. Specimen referred to the Pathology Committee of the Section.

Dr. Victor Bonney read two short communications:

(*a*) *Case of Pre-Eclampsia at the 24th week treated by Cæsarean Section.*

(*b*) *Case of Cæsarean Myomectomy with remarks on the operation.*

(*a*) The first concerned a case in which a primigravida, 24 weeks pregnant, was suddenly seized with symptoms of acute pregnancy toxæmia. The urine was much diminished in amount and contained a quantity of albumen and blood. Marked jaundice developed and rapid loss of sight occurred. Immediate evacuation of the uterus being indicated, this was effected by performing abdominal Cæsarean section. The toxæmic symptoms disappeared within two days and the patient made a rapid recovery.

(*b*) The second case was that of a primigravida whose uterus was the seat of six large fibroids in addition to the pregnancy. Cæsarean section was performed at term and after the child had been delivered the tumours were enucleated. The largest of them was the size of a melon, and was submucous in position.

The speaker submitted that this operation, which he termed Cæsarean myomectomy, should be the operation of choice in all cases of pregnancy, complicated by fibroids in which the uterus was uninfected. When pregnancy occurred in a fibroid uterus the functional value of the organ was proved, and it was worth conserving. Moreover the retractile state of the musculature was peculiarly favourable for enucleation.

Remarks on the foregoing were made by Dr. Williamson, Dr. Routh, Dr. Blacker, the President, Dr. Maxwell, and Dr. Eden.

Mr. Beckwith Whitehouse (Birmingham) read a paper on

"THE RELATION OF SYPHILIS TO THE UTERUS."

The author pointed out that the occurrence in the uterus of lesions, the result of syphilitic infection had long been regarded as extremely rare. Apart from the occasional record of a primary chancre upon the portio vaginalis of the cervix uteri, or the suggestion that some ulcerations in this area might be of syphilitic origin, very little had been written upon the subject. If it was true that the corpus uteri possessed a definite immunity to the ravages of the spirochæta pallida it was a matter of considerable interest, especially as the relationship was so intimate in connection with placental and fœtal syphilis. He did not think that this was the case, but considered rather that syphilitic lesions of the uterus had been overlooked in the past. In 1912 he had suggested that the underlying pathological factor in some cases of chronic metritis and fibrosis uteri might be syphilis. He had since had an opportunity of investigating by means of the Wassermann reaction, sixteen patients with a clinical diagnosis of this nature. Seven of these cases showed a well marked positive reaction, although only one gave a history or presented other evidence of direct syphilitic infection. In three patients it was necessary to remove the uterus on account of severe hæmorrhage unrelieved by repeated curetting and various intra-uterine applications. The uteri obtained from these cases all showed well-marked fibrosis and peri- or endarteritis of the vessels. The pathological picture coincided with the appearances seen in interstitial myocarditis, orchitis, hepatic cirrhosis and other indurative conditions which were generally accepted as being due to syphilis. The author asked, therefore, why, in the case of the uterus, was it necessary to call for other factors such as inflammation due to septic causes, repeated pregnancy, etc., to account for an exactly similar lesion, especially when the Wassermann test showed that a certain proportion of such patients were undoubtedly infected. The exact proportion that syphilitic fibrosis of the uterus bears to fibrosis due to other causes must, however, remain undetermined until a longer series of cases could be brought forward. It is possible that errors may arise even in a long series owing to the phenomena associated with "Latent Syphilis." Knöpelmacher and Lehndorff have shown that 50 per cent. of the mothers of syphilitic children give a positive reaction some years after the birth of the last child, although a few months after parturition 90 per cent. of such women react positively. The author was of opinion that it was largely from this class that the ranks of the chronic metritis patients are filled.

He then drew attention to the fact that some cases of pyometra unassociated with malignant disease appeared to bear a distinct relation to syphilis. He had seen two well-marked examples in patients who exhibited indubitable evidence of syphilitic infection, and he had received records of two others.

In conclusion he referred briefly to observations recently made upon the menstrual blood collected through an intra-uterine catheter during the secondary stage of syphilis. Specimens from five cases had been investigated, and in two the intra-cellular bodies described by McDonagh and Ross had been found. The presence of such bodies in the menstrual discharge is important as proving a possible source of infection to the uterine tissues through which they pass. At present the spirochæta pallida has not been demonstrated in the menstrual blood.

Remarks were made by the President, Dr. Amand Routh and Dr. Blacker.

Mr. M. J. Stewart (Leeds) introduced a case of

"FŒTUS ACARDIACUS AMORPHUS."

He gave an account of a typical example of the fœtus acardiacus amorphus (with drawings and radiographs) the specimen of which was shown, together with radiographs and microscopic preparations of the viscera. The monster occurred as the twin of a healthy male child, and was born half an hour before it. The parents were healthy, and the pregnancy had run a normal course.

The specimen shown consisted of a trunk-like mass without head or limbs, to the flattened ventral aspect of which the umbilical cord was attached. There were nates at the posterior extremity, with an anus-like dimple between, and ventral to the latter, two other mesial dimples, possibly corresponding to genital and urinary apertures respectively. Two small thumb-like projections were present in the position of the lower limbs. At the anterior extremity there was a mesial, ventrally placed vesicle filled with fluid, and laterally, two small dimples in the position of the upper limbs. Radiographic examination showed the presence of a vertebral column of eighteen segments, to the upper seven of which ribs were attached. Posteriorly the pelvis was represented by two bones on each side, but of limb bones there was otherwise not the slightest trace.

Dissection of the monster with subsequent microscopic examination showed the presence of liver and bowel, kidneys, ureters and testes, but heart, lungs, spleen and adrenals were all absent.

The paper was discussed by the President (Dr. Griffith) and Dr. Blacker.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, November 7th, 1913.

The President, M. J. Gibson, M.D., in the Chair.

FIBROID UTERUS REMOVED AFTER CÆSAREAN SECTION FOR OBSTRUCTED LABOUR AND PLACENTA PRÆVIA.

The President exhibited this specimen, and said that the patient, whose age was 36, was unmarried, and had had a child six years previously. She had been admitted to hospital, having had hæmorrhage for several hours previously. She also had some weak labour pains, which succeeded the onset of the hæmorrhage, and had been examined at least three times by a "handy woman," then by two students, and afterwards by the clinical clerk. She had then lost a large amount of blood, and the clinical clerk packed her vagina with iodoform gauze before moving her into hospital. When this was completed she refused to go to hospital, but when the hæmorrhage began to appear through the plug some hours later she consented. When she was admitted she was bleeding steadily, though not profusely, and was collapsed. Examination showed that the pelvis was obstructed to a very large extent by the fibroid, which could not be pushed out of it, and protruding through the cervix the edge of the placenta could be felt. During the examination a considerable quantity of blood escaped from above the tumour. The fœtal heart could not be heard. He decided to remove her uterus immediately after the Cæsarean section, because she was probably septic. She was kept alive during and immediately after the operation with much difficulty, and finally made a good recovery. The specimen raised important questions. Firstly, the value of Cæsarean section for the immediate control of hæmorrhage in placenta prævia; secondly, the treatment of a single large interstitial myoma after Cæsarean section; and, thirdly, the value of hysterectomy in cases which are probably septic.

CANCER OF THE OVARY.

Tho President, in exhibiting this specimen, said it had been removed from a patient, æt. 63, who had never borne a child. She stated that she had noticed the increasing enlargement of the abdomen, but that she had suffered very little pain. A large tumour could be felt, partly cystic and partly solid. When the abdomen was opened the diagnosis of malignant degeneration of an ovarian cyst was made, and the tumour was removed entire, together with the uterus and the other ovary *en masse*. The patient made a good recovery.

The **President** also showed sections from another case in which the ovaries and uterus had become cancerous in a patient whose breast had previously been removed for cancer. The points raised by the first specimen were the necessity for removing all the cysts of the ovary entire and the need for removal of the other ovary and uterus in cases of cancer.

Dr. **Gibbon FitzGibbon**, referring to the second exhibit, considered it of interest to hear of involvement of the uterus from an ovarian tumour. He inquired if the malignancy in the uterus was of the same character as that of the ovary, and if there was any evidence of metastasis in other parts of the body. He did not think a cyst should be tapped where it could be got out whole, an incision of two or three inches additional length was to be preferred to running the risk of fluid getting into the abdominal cavity.

Dr. **Jellett** said that if the child was dead at the time of the operation he would have preferred to have left it in the uterus, and not to have done a Cæsarean section, as this lessened the risk of spreading any infection that might have been in the uterine cavity. In cancer of the ovary he agreed with the view taken by Dr. FitzGibbon, that the second ovary should always be removed, but did not know whether it was necessary to remove the uterus also, as metastases from the ovary to the uterus were unlikely. On the other hand, removal of the uterus permitted a better clearance to be made of the broad ligaments, and so might be wise.

Dr. **Gibson**, in replying, said that in the case of fibroid uterus he performed a supra-vaginal hysterectomy and drained the abdomen through the open cervix, having stitched the peritoneum anteriorly and posteriorly to its edges. The only reason that the child was removed during the operation was that the pregnant uterus and tumour made a very large mass, and he considered that the operation could be completed more rapidly if the uterus were empty. He consequently made the transverse fundal incision and dropped the uterine contents out of the uterus by anteflexing it over the pubis. He did not touch the cavity of the uterus. The placental site continued to bleed, and having packed the cavity with a large strip of iodoform gauze, he proceeded to do the hysterectomy as rapidly as possible. The patient at this time was very collapsed. In the case of cancer of the uterus and ovaries following removal of the breast, the cancer in uterus and ovaries was of the same nature. He considered that the uterus and other ovary should be removed in all cases of cancer of the ovary.

SUBMUCOUS MYOMA REMOVED BY MYOMECTOMY.

Dr. **Jellett** said the patient E. M., æt. 30, was admitted on October 18th, 1913. She had been married three months, and had not been pregnant. She complained of a tumour, which she first noticed a year and a half previously. It was then about the size of an orange, and had been growing steadily ever since. She also complained of menorrhagia, some dysmenorrhœa, leucorrhœa, and frequency of micturition. The urine was normal, bowels regular, and heart and chest normal. When examined, the abdomen was found to be occupied by a tumour reaching up to the umbilicus, hard, and incorporated with the uterus. A submucous myoma, the size of a large orange, was found projecting from the cervix, and probably continuous in the tumour above. Around this the cervix could be felt very much thinned out and dilated.

FULL-TIME EXTRA-UTERINE PREGNANCY WITH UTERUS.

Dr. **Jellett** said the patient K. W. was admitted on June 12th, 1913, æt. 38, married fifteen years. She had had four children at term, four abortions, and was pregnant at term when admitted. Her history was one of amenorrhœa since September, 1912. On the 29th of the following April the patient had what she regarded as labour pains, accompanied with vomiting. She stayed in bed for a week; the pains ceased, and since then she had "felt no life." She stated that she noticed her stomach getting smaller since then, and complained of some discharge and a bad taste in her mouth. The urine was almost normal, containing only a slight trace of albumin. On admission, the top of the fundus was just above the umbilicus. No fœtal heart heard. Two days later—that is, June 14th—an attempt was made to induce labour by Krause's method. The cervix seemed somewhat hard and small for a pregnant cervix, but nothing else abnormal. Bimanual examination made, but no information got, mainly because patient straining hard under anæsthetic. Two bougies were inserted gently through external os, and allowed to take their own direction in usual way. There was no resistance to their passage. Tents were also inserted, and the vagina packed with iodoform gauze in sterile glycerine. On the following morning labour had not come on, the tents and bougies were removed, more tents inserted, and the vagina packed as before. Next morning, June 16th, still no labour pains, so the tents were removed. Fœtal head felt low in posterior fornix. A foot was brought down, the head pushed up, and the child extracted, during which the cervix seemed to tear behind. Fœtus was macerated. On attempting to remove the placenta manually, the hand entered a cavity, and a much larger cavity was felt on right, extending up towards the liver. No placenta could be felt, but a piece of omentum came down and the intestines could be felt. Laparotomy was immediately performed, and the following was found:—Free blood, but not much. The placenta was free, and was removed first. What was evidently an abdominal pregnancy was then discovered, the sac apparently originating in right broad ligament, extending out towards the left, and up on right towards the liver. The posterior lip of the cervix was torn, the tear extending downwards across posterior fornix. The lower part of the uterus seemed very friable. Supra-vaginal hysterectomy was done, and the sac packed with gauze, the end being pushed out through the tear in the posterior fornix, and the cavity stitched together over the gauze. Two bimanual examinations failed to reveal the presence of a small uterus, this condition being only discovered on laparotomy.

Dr. **Tweedy**, referring to the myomectomy that had been performed previously by him on this patient, asked for fuller details as to the operation.

Dr. **Rowlette** said that an examination of the uterus from the pathological point of view gave no assistance. He suggested that, having regard to the fact that six weeks previously the patient, who lived in the country, had labour pains, the uterus at the time ruptured, and allowed the greater part of the ovum to pass into the abdominal cavity, and that the uterus then involuted.

Sir **William Smyly** said that the difficulty in his mind was, where did the pregnancy originate? The ease with which the uterus ruptured with quite extraordinary.

Dr. **Neill** recalled a case very much like this that had been treated in the Coombe Hospital. The foot of the fœtus was brought down and allowed to remain so for several hours, and then extracted. It was smaller than that shown in the present exhibit. After getting the fœtus, an effort was made, without effect, to get the placenta. There appeared to be an edge to be felt, but he did not attempt to remove it, as the patient was in a very bad condition, and died the following morning. There was a history of bleeding in previous pregnancy. Partial *post-mortem* examination showed the uterus to be as large as the fœtal head, and there was an old tear. A ragged placenta was discovered attached to the sigmoid flexure. The theory in this case was that the uterus ruptured and the fœtus slipped out.

Dr. **M'Allister** asked if the placenta was frequently found separated in such a case. He suggested that at the time that the patient had the pains rupture might have occurred by the placenta having eaten its way through the uterus, and in this way the fœtus might have escaped.

The President asked what was found when the abdomen was opened. He recalled a case of extra-uterine pregnancy at full term. In this, when the abdomen was opened, the child was removed alive from the bag of membranes. There was severe hæmorrhage from the placental site, which was immediately controlled by compression of the aorta, and afterwards by a firm pack of gauze. The placenta was attached to the ruptured left tube, the posterior layer of the broad ligament, and to the lower bowel and the tissues about it. The gauze was removed gradually, the last piece on the twelfth day. The patient made a good recovery and the child survived. He had never seen a case of ruptured uterus in which the uterine contents had escaped unruptured into the peritoneal sac. The child in every case lay free among the intestines. The fact that the child in this case had lain in its membranes outside the uterus was in favour of the case being one of extra-uterine pregnancy.

Dr. Jellett, in replying, said that the cervix was dilated in two ways—(1) by the two sets of the sea-tangle tents, and (2) by the tearing of the posterior lip during the delivery of the fœtus. The sac of the ovum was adherent to the intestine and omentum—a fact which disproved Dr. Rowlette's suggestion of the extrusion of the ovum through a rupture of the uterus six weeks before the patient came to hospital. It was found impossible to remove the sac at the operation, and it was left, being plugged as tightly as possible with iodoform gauze, but the membranes gave no subsequent trouble. He considered that if one knew the state of the left tube the nature of the case would be clear, but, unfortunately, this tube was not in a recognisable condition at the time of the operation, owing to the effect of the extravasated blood on the peritoneum. Dr. Tweedy's previous myomectomy was done on the anterior wall of the uterus, and he, Dr. Jellett, did not consider that it had any effect in producing the condition met with. He would like to emphasise the fact that neither Dr. Madill nor he himself had the least idea that they were not dealing with an intrauterine pregnancy until the abdomen was opened after the rupture of the gestation sac.

Referring to the second case of myomectomy, his reasons for operating through the vagina were—(1) that he wished to save the uterus, and (2) that he was afraid of doing an abdominal myomectomy on account of the risk of infection owing to the manner in which a large part of the tumour protruded through the cervix into the vagina.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held November 28th, 1913.

The President, Mr. A. Ernest Maylard, in the Chair

Mr. Henry Rutherfurd showed (1) a case of plexiform neuro-fibroma in a girl æt. 8 years, with hypertrophic and pigmentary changes in the skin and some angeiomatous patches, atrophy of muscles, and atrophy or rarefication of bone as indicated by repeated fractures and verified by skiagraphs.

(2) A case of cystic disease of bone (upper end of humerus) in boy æt. 14 years, treated by free opening up and implantation of bone. The patient was shown with skiagraphs before and after operation.

(3) Gall-bladders removed in conditions of cholelithiasis (four recent cases), with microscopic preparations.

(4) (With Professor J. H. Teacher) the spinal column of a boy æt. 6 years, the seat of multiple tuberculous foci (upper cervical, dorsal, and lumbosacral).

Dr. A. Louis McIlroy made a short communication on a

CASE OF CHORION-EPITHELIOMA

and one of

MYOMATA COMPLICATED WITH PREGNANCY

and showed coloured photographs. In the first case, that of a patient aged 30, a diagnosis of incomplete abortion was made, and on microscopic examination of the curettings, Dr. Teacher found chorion-epitheliomatous tissue. Panhysterectomy was performed with complete recovery. In the second case the patient, æt. 30, had been married six years and was sterile. Dysmenorrhœa and menorrhagia had been present. On examination a diagnosis of pregnancy with ovarian cyst was made. On the onset of uterine hæmorrhage the patient was examined under an anæsthetic and myomata with pregnancy diagnosed. Supravaginal hysterectomy was performed, and on section of the specimen a $4\frac{1}{2}$-months fœtus was seen. In the wall of the uterus were several myomata, one of which showed marked degenerative changes. The patient's health was markedly improved after operation.

Dr. J. W. McNee read a paper on

RECENT WORK ON THE ÆTIOLOGY OF GALL-STONES,

which will be found under the heading of "Original Papers," page 670.

FRANCE.

Paris, Dec. 13th, 1913.

Typhoid Fever in Children.

The clinical characters of typhoid fever in children differ somewhat from those observed in adults. The *début* is frequently brusque, without prodroma, while two symptoms, says Dr. Pater, almost special to children are frequent, vomiting and abdominal pain.

The vomiting is alimentary at first, becomes rapidly watery and even bilious. The abdominal pain can be moderate, diffused or sharp and localised in the right iliac region leading one to think of appendicitis. In about half of the cases of typhoid fever in children this abdominal pain is felt. At the end of the first week of the disease it generally disappears or it may persist with diarrhœa.

The rose-coloured spots or petechiæ are present as in the adult; tumefaction of the spleen is also observed in the majority of cases. The temperature varies more in the child than in the adult; ascension is more rapid and defervescence more prolonged.

As to complications, the gravest concern the heart, the brain and the intestine. That of the heart is characterised by tachycardia, pallor of the face, cold extremities, cardiac depression terminating frequently in collapse and death.

Subacute meningitis is, naturally, of extreme gravity; the same may be said of intestinal hæmorrhage where perforation is to be feared. There is one secondary symptom syndroma sometimes observed and generally mortal, green diarrhœa accompanied with vomiting and a sudden fall in the temperature.

Relapse in typhoid fever of children is frequent, consequently the period of convalescence should not be neglected, no change in the *régime* followed during the course of the malady should be allowed, nor should the patient leave his bed until 15 days have elapsed since the definite fall in the temperature.

Rheumatism.

Salicylic acid, 1 dr.
Antipyrine, 1 dr.
Bromide of potassium, 1 dr.
Ext. of belladonna, 6 grs.
Ext. of opium, 5 grs.
Essence of turpentine, 1 dr.
Vasoline, 1 oz.
Lanoline, 1 oz.

Rub into the inflamed joint, apply a layer of cotton wool and cover with oil silk.

Tuberculous Ulcerations.

Every five days canterise the surface with

Nitrate of silver, 15 grs.
Distilled water, 1 dr.

Touch the parts once a day with
Lactic acid, 1 oz.
Water, 2 oz.

Dress with iodoform and destroy when necessary the peripheric nodulæ with the thermocautery.

ALCHOLISM IN FRANCE.

Alcoholism, tuberculosis and syphilis are ravaging France, and participate in a large measure in its decreasing population.

An engineer of no small merit, M. Jaquet, has just published a book on alcoholism, sounding a note of warning on the havoc it is causing among the working classes.

The working classes, says the author, consume four-fifths of the alcohol manufactured in France. This "national peril" has become an important factor in the development of tuberculosis, criminality and lunacy.

M. Jaquet proposes three methods for dealing with the subject: Educating the masses by means of the public schools, conferences given by doctors, sociologists, officers in the barracks, etc. Legislation—prohibition of absinthe, limitation in the number of drinking shops, rigorous application of the laws on drunkenness, increasing the duties on alcohol, social measures which by improving the material condition of the working classes will raise their moral level.

The cultivation of the vine in France covers 1,760,000 hectares (2½ acres). The produce insures to the proprietors an annual revenue of 1,100 millions of francs. The manufacture of alcohol attains annually 2,500,000 hectolitres (22 gallons) of the value of 125 million francs. Five million persons are more or less employed in the alcohol traffic. The State duties represent 12 per cent. of the total revenue.

GERMANY.

Berlin, Dec. 13th, 1913.

AT the Urological Society, Herren Roth and Meyer read a paper on

URETHROSCOPY OF THE POSTERIOR PART OF THE URETHRA.

The investigations were carried out by the instruments of Goldschmidt and Wossidlo. The material on which the results were founded was very large. The most frequent cause of morbid changes in the posterior urethra was gonorrhœa of the chronic form. In 20 per cent. of the cases examined, polypi were met with, granulations, etc. In a great number of these cases there were no subjective symptoms. A similar condition of the mucous membranes was present in cases of sexual neurasthenia. These were not, however, the cause, but the result of the nervous condition. The frequent result in general treatment of these cases was in favour of this assumption, and was in contrast to that of Ollawski. In most cases of sexual neurasthenia the affection might be caused by abstinence, morbid sexual perversions, venous engorgement, the engorgement leading to the mucous changes mentioned. A similar condition was met with in impotence. Treatment was limited to caustics and the cautery. Through the treatment a serous saturation was brought about that led to a state of irritation in which the centre for erection was implicated. Upon the whole, however, the treament was mainly general. In about 80 per cent. of the cases relief was obtained by these means alone. The effects of caustics and cautery were not always lasting. The speakers thought too much had been made of the local changes, and this exaggerated belief in their importance had led to meddlesome treatment that was not necessary or advisable.

At the Verein für Innere Medizin, Hr. Guggenheimer contributed a note on

AUXAUTOLYTIC MATERIAL IN PATHOLOGICAL SERUM.

He said there were substances in blood serum that advanced autolysis of certain organs. He had, therefore, named them auxautolytic substances; he considered it probable that they were of the nature of ferments. He first attempted to influence autolysis of the human brain by human serum, led thereto by the peculiar behaviour of the albuminous fractions in syphilitic serum. The effects were negative, however; he could not effect any noticeable influence. On the other hand, serums from three cases of croupous pneumonia and serum from a case of uræmia did influence autolysis of the brain. The strengthening of function was considerable. Autolysis of the rabbit's liver also was frequently influenced by serum of croupous pneumonia and chronic nephritis; a similar effect was produced by the blood serum from a case of diabetic coma and also from one of commencing delirium. This auxautolytic serum was not derived through any changed reaction of the blood, nor through pharmacological agents, nor from a diminution of the quantity of complement. The appearance of these auxautolytic substances pointed to the existence of intravital autolytic processes. In discussing how far there was any relation between Abderhalden's protective ferment and the serum material described, he said there was a possibility that there was a specific autolytic organ-enzyme that passed into the blood. With this opened a prospect of demonstrating clinically some elective auxautolytic action.

Hr. Pincus had found that pneumonic serum disintegrated fibrin in the crises. That the protective ferments did not come from the leucocytes was shown by the fact that they were present in undiminished numbers in animals that had been rendered free of leucocytes by the action of thorium X. He also held it to be probable that the protective ferments in the blood were escaped organ-ferments, heterolysines in Jacoby's sense.

Hr. Jacoby also held Abderhalden's protective ferments to be an outflow of organ-ferments into the blood. It had to be assumed that there were serum substances in the blood that increased the action of ferments.

AUSTRIA.

Vienna, Dec. 13th, 1913.

WHOOPING COUGH.

AT the recent meeting of the K.k. Gesellschaft in Vienna, a girl, æt. 3½, was exhibited by Dr. F. Hamburger, who had been cured of whooping-cough of five weeks' standing by two days' treatment with faradisation. This case, accordingly, furnished a typical illustration of the fact that whooping-cough, when it has lasted for five or six weeks, comes in many cases to be modified, clinically and pathologically, so far as to be correctly regarded as a neurosis; inasmuch as the affected children, long after the true disease has actually quite disappeared, continue to display the regular recurrence of the paroxysms of coughing with all their specific characteristics. Dr. Hamburger distinguishes, in the course of a case of whooping-cough, a stadium organicum and a stadium neuroticum; that is to say, a stage in which the paroxysms must take place, as the necessary consequence of the specific alterations of tissue, and a stage in which, notwithstanding the complete resolution of the organic changes, the paroxysms continue to be repeated in way of semi-voluntary reflexes. In the great majority of cases the organic stage does not last more than five or six weeks, and it is accordingly desirable, at the close of this period, to commence a course of energetic treatment by suggestion, for which purpose the employment of the faradic current is specially suitable. By its judicious application, the intensity and frequency of the paroxysmal attacks of coughing can often be diminished to a conspicuous degree in a very short time; and those of the whooping-cough proper be made to disappear completely. To the query of Dr. S. Federn whether cases of whooping-cough continue to be infective during the neurotic stage, Dr. Hamburger replied that it was then to be regarded as such in those cases only in which the patients happened to be carriers of bacilli.

RECTAL CARCINOMA: RADIUM TREATMENT OF SAME.

Dr. O. v. Frisch exhibited a recent specimen of rectal carcinoma which had been treated for many months with radium radiations, and had been subsequently extirpated by him. The carcinomatous tumour had conspicuously diminished in size during the radium treatment, but a firm rind was formed in which the whole pararectal tissue was embedded. This callous thickening of the pararectal connective tissue is an unusual condition, and is possibly analogous to the changes which have been observed after radiation treatment of struma. This fact suggests that it may be attributed to the radium.

Dr. O. Schindler then described the radium treatment of the rectal carcinoma of which the specimen had been exhibited by Dr. Frisch. The radiation agent that he had employed was a Dominici tube, which contained 28 milligrammes of radium bromide. The primary rays were filtered through a sheet of platinum of 0.8 mm. in thickness, and the feeble secondary rays were intercepted by thickly-gummed glove fingers. The total result was the application of about 6,000 mg. radium bromide within a month, and so arranged that about 2,000 mg. radiations had been applied *in continuo*. A pause was then made. Such pauses proved to be necessary in the treatment of rectal carcinoma—on the one hand to give time to the organism for transforming the products of cell destruction into innocuous materials; and, on the other hand, in order to keep within bounds the symptoms of local irritation (tenesmus and strangury), which were specially likely to occur during the radiation treatment of rectal carcinoma, more especially the strangury in cases in which the growth had infiltrated the wall of the bladder. A higher dosage appears to him to be inadvisable; inasmuch as a constant regard must be had to the danger of perforation of the bladder on account of the infiltrating adhesion of the neoplasm to the wall of that viscus.

Theory and Treatment of Diabetes.

The discussion of Dr. W. Falta's communication on "The Theory and Treatment of Diabetes" was again resumed, and concluded. Dr. O. Pick discussed the ætiology of diabetes mellitus, which must, he believes, be sought for in some instances in neural sources; the primordial germ having been stimulated to unhealthy activity by respectively psychic agencies.

Dr. Reach emphasised the view that in the so-called carbohydrate cure the carbohydrate itself may not be the effective agent; it must, however, express its influence in every form in which it may be used: for example, in that of bread. But we should bear far more constantly in mind than hitherto has been done the fact that in the respective aliments other, and still unknown, compounds are present, which confer upon them their own individual therapeutic value (but which, in the case of bread, are transmuted or destroyed in the process of baking).

Dr. W. Falta, in the course of his concluding reply, dealt with the various objections and arguments of the speakers. With regard to the importance of fats for realisation of the value of carbohydrates in the carbohydrate cure, the results of experiment had shown that, with regard to this realisation, the result was apparently the same whether much or little fatty matter had been added to the soups or other aliments used by the patient. The fact that absorption of carbohydrates is retarded by the presence of fatty matters is unquestionable. But the pleasing illustration furnished by the knowledge that cereals, in the form of soups, are so much better tolerated, even than bread, did not seem to him of any consequence in this connection. In this clinico-chemical analysis he attributes the principal importance to the fact that the cereals, in the baking and cooking, undergo a physical process of unfolding by which their adaptability to the physiological process of absorption is very much altered.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

Indian Students and their Grievances.

A meeting of fully 100 Indian students was held in Edinburgh last week to determine the attitude which should be taken up towards the newly appointed sub-committee of the Advisory Council to inquire into the alleged grievances of the students against educational or other bodies. The general tenor of the speeches made at the meeting was that the sub-committee's inquiry ought to be discouraged. To lay grievances before such a body would be to admit the guardianship of the India Office, and to acknowledge and strengthen the position of the local adviser, to whose presence objection was taken. One of the speakers said that they had no educational grievances, and that the creation of a department to bring about better relations between them and a certain section of the students was a sham. One cannot but admit that there is some reason in the position taken up by the students; certainly no offical inquiry can establish harmonious relations where good manners and good taste are wanting. At the same time, ventilation of the question would probably do good, and the refusal of the Indian students to co-operate is obviously determined by dislike of the idea of being in any respect under the authority of the India Office rather than by anything else.

Edinburgh School Children.

The work of the School Board for the year was under review at the Board meeting last week, and in connection therewith a few matters of medical interest were brought up. Free dinners are now supplied to necessitous children, of whom the largest number on the free food roll was 757, during the third week of February. The total number of pupils on the roll was 40,260. This year, 1,011 children received free meals, as against 1,517 last year. The scheme of supplying penny dinners to semi-necessitous children has probably contributed to the marked decrease in the number of applications for free meals. The net cost to the Board of the feeding scheme was £1,861. During the session, 1,940 children were supplied by the police with boots and clothing. An important development during the year has been the provision of medical treatment for needy children. Hitherto, though inspection has been in force for five years, treatment has not been undertaken except in so far that parents have been guided as to which of the voluntary agencies (dispensaries, and so on) they should seek for advice. In many cases notices of this kind to parents were ignored. In 1913 the sum allocated to the Board for medical treatment was £850, and in view of this the Board decided to establish a medical clinic for treatment. This policy was considered the most expedient, as the money was available only in so far as it was actually to be expended during the year; by fully equipping such a clinic from the beginning, any further grants could be devoted to actual treatment. Premises were accordingly leased in Lauriston Place as a medical treatment centre where defective teeth, defective vision, and minor diseases of the ear, nose, and throat can be dealt with. The staff consists of four dentists, one oculist, and two nurses. Since January 16th and up to the end of last session there have been 5,251 attendances by pupils, 993 for visual defects, 1,644 for dentistry, 1,680 for external eye disease, 221 for ear disease, 41 for skin disease, and 672 for the fitting of spectacles.

Presentation to Dr. Melville Dunlop.

On the occasion of his retirement from the staff of the Edinburgh Sick Children's Hospital after 27 years' service, Dr. G. H. Melville Dunlop was entertained to dinner on December 12th by his colleagues on the staff and his old residents, and was presented with a piece of silver plate in token of their affection and esteem, and in commemoration of his long association with the hospital. Mr. H. J. Stiles presided at the dinner, and Dr. J. W. Simpson acted as croupier.

Appointments under the Triple Qualification Scheme.

At a meeting of the Committee of Management of the Triple Qualification of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow, held on Friday last, the following appointments were made:—Mr. D. L. Eadie, 50 George Square, Edinburgh, Inspector and Treasurer; and Mr. Walter Hurst, 242 St. Vincent Street, Glasgow, Registrar for Glasgow.

GLASGOW.

Allocation of the Surplus under Medical Benefit.

At a meeting on the 10th inst. of the Glasgow Burgh Insurance Committee, the subject of the surplus on the head of medical benefit and its allocation was again discussed, but no solution of the question was reached. Mr. Hamilton Brown moved the approval of the minutes of the sub-committees who had been considering the subject. These recommended that the unappropriated insured persons should be allocated equally among the practitioners on the panel whose lists do not exceed a maximum of 1,500; so however, that no list should be increased beyond that maximum, that payment should be made in full of all "identified" and "unidentified" medical forms, after exclusion of duplicates, etc.; and that the balance remaining in the panel fund, after meeting the payments to the practitioners on the panel as above, should be distributed among those practitioners proportionately to the number of persons allocated to them and to the period they have been on the panel, on the understanding that the payment was to be in full settlement of the medical accounts for the year. After discussion, it was decided to send the whole matter back to the Medical Benefit Sub-committee for further consideration.

The Society of Alchemysts.

At a meeting on the 11th inst. of the "Honourable Alchemysts" in Glasgow University, Mr. F. Soddy, F.R.S., described the most recent ideas in connection with the structure of the atom. He spoke of the work of Mosley in Professor Rutherford's laboratory in Manchester, and pointed out that this, taken in conjunction with previous work on the characteristic rays of different elements and with the work of Mr. Fleck (who gave an address at the same meeting), led to the belief that the atom was composed of three concentric spherical shells. The innermost one consisted of the "nucleus," containing positive and negative charges concentrated in a sphere the diameter of which was the 10,100th part of the diameter of the atom. The intermediate shell consisted of electrons, which gave rise to the characteristic gamma radiations. The chemical properties of the substance were determined by the number of electrons in the outermost shell.

BELFAST.

Belfast Medical Guild.

A special general meeting of the Belfast Medical Guild was held in the Medical Institute, Belfast, on the 5th inst. The object of the meeting was to ascertain the feeling of the profession as to the advisability of continuing the Guild. In the absence of the President, the chair was taken by Mr. Andrew Fullerton. On account of the establishment of the local Medical Committee in connection with the Insurance Act and the increased interest taken in the meetings of the Belfast Division of the British Medical Association, it was felt by some that the need for the Guild no longer existed. In addition, the large number of meetings in connection with the various medical organisations have proved a tax upon the time of the busy practitioner, and it was thought that it might be wiser to concentrate his energies upon the older organisations. After full discussion, however, it was finally decided to continue the Guild, keeping in view the more social side of professional life until a crisis such as that through which we have just passed should arise, when the Guild should again assume more of a medico-political function. The new lines upon which the Guild will be run will be discussed at the annual meeting, to be held at the beginning of the year.

Belfast District Lunatic Asylum.

At a meeting of the Committee of the above institution, held on the 8th inst., Dr. Norman B. Graham was appointed Assistant Medical Officer, in place of Dr. Patrick, resigned. Dr. Patrick has been Assistant Medical Officer for the past seventeen years, and has just been appointed Medical Superintendent of Omagh Asylum. We congratulate Dr. Patrick on his well-earned promotion, and we believe that the interests of Omagh Asylum are safe in his hands.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

FINANCIAL REFORM IN THE BRITISH MEDICAL ASSOCIATION.

To the Editor of The Medical Press and Circular.

Sir,—Lately we have had several leading articles upon the B.M.A. I have always read them with interest, though I cannot always say with approval. You tell us that the loss of the Association would be irreparable; and I entirely agree with you. Has it ever occurred to you that you may—unwittingly, I know, be assisting to bring about its downfall? Have you no readers who are not members of the Association and who may be in doubt whether they should join the Association or not? Do you think that, after reading your articles, they would decide to join; or do you think that their attitude would rather be this: "I thought of joining the B.M.A., but I am convinced that it would be a foolish action on my part to join so badly managed an Association"?

With regard to raising the subscription to £2 2s. Is it too much to ask a medical man to pay £2 2s. a year to have his life interests guarded by the Association? Because, after all, the majority of us have to live by our profession. What was the result of the roll call: Ayes, 131; noes, 42; not voting, 2? Now, these representatives had been instructed how to vote by the members of their divisions—a point worthy of note.

My own personal opinion is, and has been since the dawn of the Insurance Act, that the subscription should have been raised then, to assist the funds which were so strained by the fight: which would have been won if the members of the Association had hung together. Do not you think that, if you mean that the loss of the B.M.A. to the profession would be irreparable, instead of publishing the sentence that the raising of the subscription is an astonishing ineptitude and that it will lead to a large number of resignations, it would have been wiser to have helped the Association by remarking that no loyal member of the Association who has the best interests of his profession at heart would think of resigning because he will be called upon to pay 17s. more per annum—which works out at about 3¾d. a week—for his privileges.

I am pleased to note that the advertisement rates have been raised. This is a step in the right direction. I am a member of the B.M.A. For many years I have been a subscriber to the Medical Press and Circular as well as a contributor, and I hope that if you publish another article on the B.M.A. it will throw oil on the troubled waters and not stir them up and lash them into fury. Let me suggest as a text, "The Loss of the British Medical Association to the profession would, in our opinion, be irreparable." Point out the various ways in which it would be irreparable, and stimulate your readers to support it loyally in every way. Furthermore, you can do unlimited good to the Association by firing with enthusiasm those members who take no personal interest in the work of the Association, but who, nevertheless, grumble if things do not turn out as they expected they would.

I write this letter in no carping spirit, but because at the present time the Association requires all the sympathy possible of its well-wishers.

I am, Sir, yours truly,
S. J. Ross.

Bedford, December 10th, 1913.

[It would be unnecessary to point out to so distinguished a medical critic as Dr. Ross that it is sometimes necessary to be frankly and even apparently brutally outspoken in order to save a sick man. That is the spirit of friendly candour in which our criticisms were made. We note that our esteemed correspondent has not attempted to analyse the issues raised as to the need of domestic and financial reform of the B.M.A., but has rather addressed himself to an *ad misericordiam* appeal to us to avoid words of harshness, and to hope for better things in some hazy future. Why should not plain business methods rule our medical organisations?—Ed. M. P. and C.]

To the Editor of The Medical Press and Circular.

Sir,—If you are not already aware of it, your publisher can inform you that I have been a subscriber to the Medical Press for upwards of 25 years. For more than half that time I have also been a member of the B.M.A. I have noticed all along that you criticise the Association from a detached standpoint. You let us see ourselves as others see us. We ought to be indebted to you for this service. I am convinced that no individual or small party within the Association is entirely to blame for any of the evils which at present afflict it. The situation is due solely to the long-continued apathy of the great mass of members. It was stated at the Representative Meeting that not more than ten per cent. of members ever attend local meetings. In my own division, except during the Insurance Bill crisis, a five per cent. attendance has been the average. It has never been possible to rouse the interest, much less the enthusiasm of members on any question of Association policy. I have stated in your paper more than once, and I now repeat, that the Association has for many years filled the part almost solely of a co-operative society for the publication of a medical journal. This work has almost completely absorbed the forces and resources of the Association. A journal has been issued to members at a cheap price, but it has been produced at a stupendous cost. The paper is now four times too big. It needs an effort to lift it; it is fatigue to read it. Every part of it might be cut down with enormous advantage to the great bulk of members, the general practitioners. With a circulation of 25,000 a week, the advertisements would still come in. If the charge per page were increased the number might diminish, but advertisers would be satisfied with a part instead of the whole of a page, and there would be more chance of their announcements being seen. It is doubtful whether one per cent. of readers now ever glance through the huge mass of advertisements. The *Journal* ought to yield a profit income of at least £10,000 a year. A majority of the small meeting of my division supported the proposed increase of the subscription. I shall certainly not go on if the financial affairs of the Association do not undergo the overhaul which you insist upon. A very large proportion of members will, I am sure, adopt a similar attitude.

I am, Sir, yours truly,
An Obscure Member.

December 12th, 1913.

THE NATIONAL MEDICAL UNION.

To the Editor of The Medical Press and Circular.

Sir,—Your leading article and notes in your issue of December 10th have unwittingly done injustice to the National Medical Union of non-panel men.

The only question at issue at the Conference was the admission of non-panel men on Local Medical Committees, and possibly the signing of the contracting-out form 43 I.C. There was no difference of opinion with regard to the condition of membership—that members must be absolutely non-panel; that is to say, no medical man whose name is on a panel list or who has any connection with the panel indirectly can be a member of the Union. This does not admit of any side-door issue by which a panel man can enter.

If you will read the resolution again—and I will repeat it here: "That the principal condition of membership of the new federation shall be that applicants for membership shall not be on the panel directly or indirectly, and that all local associations shall have power of autonomy"—you will see that the words "shall not be on the panel, directly or indirectly," must exclude every form of panel practice.

It is possible that certain local associations, having autonomy, will go further and make their condition of membership absolutely non-service, and this the resolution allows. Others may allow latitude to their members to assist the Act by unpaid service on committee, etc.

It is not yet desirable to consider the question of policy. When the organisation of the Union has been completed a strong policy will be formulated,

I am, Sir, yours truly,
E. Arthur Dorrell,
Hon. Secretary.

Waldorf Hotel, London.
December 11th, 1913.

[The question raised by our correspondent hinges on the meaning of the phrase "absolutely non-panel." Men who have signed Form 43 have agreed to treat contracted-out patients under the National Insurance Act under certain contingencies. Men who have thus signed may or may not be regarded as indirectly on the panel—anyway, they are eligible for the Non-panel Union. Then again, local committees, apparently, may admit men on the panel if they see fit. If that be the correct interpretation it opens a side-door for panel men, as stated in our editorial.—Ed. M.P. and C.]

FAITH HEALING AT UNIVERSITY COLLEGE.

To the Editor of The Medical Press and Circular.

Sir,—The enclosed private and confidential statement exemplifies what may be indirectly the tragic results of performances such as that which was conducted at University College last month, and reported in the *Times* and all the leading papers in a fashion calculated to confuse and mislead the credulous and suffering public. The only person who has come out of the business without blame is Lord Sandwich. He disarms criticism by the statement that "he does not pretend to medical or surgical science." He apparently looks upon himself as an instrument chosen by Divine Providence as a twentieth century worker of miracles. "There are few serious maladies he has treated without success"; he "has never failed to relieve people in agonies of pain." The erstwhile members of the committee of the Psycho-Medical Clinic could surely have needed no analysis of Lord Sandwich's psychology in determining his fitness to take the chair at their inaugural meeting; they surely could not have needed any reminder of the mischief that might result from the promulgation of his views uncriticised or unrefuted by distinguished medical members among his audience. Why did not Dr. Constance Long or Dr. Maurice Craig perform what seems to have been their bounden duty on this occasion? What is the use of the belated disclaimer of Professor Spearman in the *Times*—a disclaimer so obscurely worded as merely to make popular confusion worse confounded. What is the use, from the public point of view of resignations announced in medical papers only, when a world-wide publicity has been given to proceedings to which eminent doctors falsely seem to have given sanction, but which they, in fact, most strongly object to?

I am, Sir, yours truly,
Scrutator.

December 13th, 1913.

[If there existed a Public Prosecutor charged with enforcement of the law, the facts stated in the document submitted to us by our correspondent would at once result in a charge of manslaughter against the unqualified practitioner involved. A large number of the victims of quackery of every kind are led on to perfectly preventable death whilst relying upon useless methods in cases easily amenable to scientific treatment.—Ed. M.P. and C.]

OBITUARY.

Dr. J. O'DONOVAN, KINGSTOWN.

With much regret we record the death of Dr. J. O'Donovan, F.R.C.S.I., of Kingstown, Co. Dublin. He was at an advanced age, and had been in failing health for some months past. Dr. O'Donovan practised with success in Kingstown for many years, and enjoyed to a remarkable extent the confidence of the public and of the profession. He was a man of high medical skill, and, more important, of high character, kindly and honourable in all relations of life. He was specially noted for his kindness to the poor and his unostentatious charity.

MR. SYDNEY JONES, OF LONDON.

We regret to record the death of Mr. Sydney Jones, M.B.Lond., F.R.C.S., which took place last week at Balham, at the age of 82, one of the best-known of the London surgeons of the latter half of the last century. After a distinguished career as a student in the Medical School of St. Thomas's Hospital, he was in 1860 appointed Assistant Surgeon to the hospital, was given charge of the ophthalmic department, and became Lecturer on Descriptive and Surgical Anatomy and Ophthalmic Surgery. In 1871 he became Full Surgeon with charge of beds and Joint Lecturer on Systematic Surgery in the Medical School. This post he occupied for the full period of 20 years, when he retired from the hospital and was made a consulting surgeon. In addition to his strenuous work at the hospital, he became a member of the Council of the Royal College of Surgeons of England and an Examiner in Surgery to the Royal College of Physicians of London. After retirement from the hospital, when he had more leisure, he became an Examiner in Surgery to the University of Glasgow. Mr. Sydney Jones was known as a surgeon whose opinion was always sound, while his help was in much request in consequence of his brilliancy as an operator. His contributions to surgical literature were not numerous, but were essentially of a practical kind. He edited a pathological catalogue of the St. Thomas's Hospital museum, and from time to time made contributions to the hospital reports, among the most important of which were papers on the excision of joints. Mr. Jones was Consulting Surgeon to the London Throat Hospital, the Surrey Dispensary, the Royal South London Dispensary, and to the Cottage Hospitals of Luton, Beckenham, and Hatfield Broad Oak.

LITERARY NOTES.

"Industrial Lead Poisoning" will be the title of a new work by Sir Thomas Oliver, to be published early in the New Year by Mr. H. K. Lewis. The book will be an elaboration of the lecture recently delivered at the Royal Institute of Public Health. The subject of lead poisoning will be dealt with mainly from the industrial point of view, and will include symptomatology, pathology and treatment of the disease. The same publisher announces also a second edition of Dr. Lewis Jones's book on "Ionic Medication," the fifth of Dr. Dudley Buxton's popular handbook on "Anæsthetics," and a fifth edition of Mr. Albert Taylor's "Sanitary Inspector's Handbook," also considerably enlarged.

* * *

Our old friend, "Hazell's Annual" for 1914, has appeared once again in due season. It is edited by T. A. Fyram, M.A., LL.D., and has been revised to November of the present year. Needless to say, the 29th issue of the "Annual" sustains the reputation of its predecessors, giving, as it does, a concise collation and review of the most recent topics of the day. There is no work of the kind, to our mind, better fitted for the library table of the medical practitioner. As a trusted book of reference, it has for many years past figured conspicuously in the consulting-room of the present writer. There is no need to recapitulate the many virtues of "Hazell." Not the least among them, by the way, is the copious index, the very reins to the literary writer. The price is moderate as ever—to wit, 3s. 6d. net.

* * *

"The Medical Who's Who" for 1914, published by the London and Counties Press Association, Ltd., 39, King Street, Covent Garden, W.C., is a far more representative biographical directory than the preceding issues. That this is so is due to the tactful and enterprising action of the publishers, for they have sent forms of particulars to every registered medical practitioner in Great Britain and Ireland. A new and welcome feature of the work is an alphabetical list of towns, with the names of resident practitioners, whose names and addresses appear in this edition, which will be found at the end of the volume. The publishers state generously that particulars are inserted "free from any condition." Some space might be economised if a limit of one column were imposed upon the entries, for all essential biographical details can usually be stated well within this space. The inclusion of the names of dental practitioners not in possession of a medical qualification raises the question as to whether it might not be better to place these in a separate list or even to publish them in another volume. It is to be hoped that in future every medical practitioner will return the form of particulars and thus assist in rendering this excellent publication truly representative of the profession.

MEDICAL NEWS & PASS LISTS.

The Opening of the Empire Hospital.

The Empire Hospital for Paying Patients, Vincent Square, S.W., was opened on Monday last for inspection previous to the admission of patients. The hospital is designed for the reception of persons of moderate means who cannot afford to enter an expensive nursing home, but who do not feel justified in accepting the charity of free institutions. It has the distinction of being the first and only institution of its kind in England. The directors are Lieutenant-General Sir James Bevan Edwards, Lord Anglesey, Lady Scarbrough, Mr. Harvey Hilliard, Mr. Benjamin Morgan, and Mr. Herbert Samuelson. The Hon. Advisory Medical Committee includes Sir Francis Laking, Sir Victor Horsley, Dr. Arthur Latham, and Mrs. Dacomb Scharlieb.

The hospital, which is constructed on the most modern hygienic principles, and in which every patient has a separate room, contains two operating theatres, one for minor and one for major surgical work, while a room has been set apart for the operative treatment of septic cases. The electric installation is complete, and comprises an X-ray room, a Nauheim bath, Dowsing radiant heat, electric light, and hydro-electric baths. Surgical, medical and obstetrical cases are received. Any physician, surgeon, or general practitioner may send his patients to the hospital, and patients are attended, in all cases, by their own doctors. A feature of the hospital is the roof garden for convalescents.

The Duke of Portland's Gift to a Hospital.

It is announced that as a thankoffering on the coming of age of their elder son, Lord Titchfield, next year, and to mark their silver wedding, the Duke and Duchess of Portland have written to the Committee of Management of Mansfield Hospital asking them to accept a sum of between £4,000 and £5,000 to liquidate the debt on the King Edward memorial wing which is being built there.

Sad Death of a Medical Man.

The death took place, on December 10th, at Tetford, near Horncastle, of Dr. James Campbell Grey, in tragic circumstances. In his house, after lunch, he took a dose of strychnine by mistake. He at once realised his error and called upon a woman, who was cleaning, to mix him an emetic, but finding this had not the desired effect, he told her to wire to the doctors at Horncastle, stating, "Come at once; have taken strychnine by mistake." The woman did so, but on her return found he was dead. Dr. J. W. Jessop, Dr. H. A. Howes, and Dr. F. Withers, of Horncastle, afterwards arrived by motor.

The deceased was L.R.C.P., L.R.C.S.Edin., and was educated at Queen's College, Belfast. Born in 1850, he commenced practice in 1874, at Wragby, and in 1877 went to Tetford, where he was panel doctor, public vaccinator, and poor-law medical officer. He was a large property owner.

The Women's Hospital for Children.

The first ward for in-patients has now been opened in the Women's Hospital for Children, 688 Harrow Road, W., the only children's hospital in London staffed by medical women. The hospital has been founded to provide general medical and surgical treatment for the sick children of a crowded neighbourhood, and to give medical women a children's hospital in which they hold staff and residential appointments and have an opportunity of specialising in children's medicine. The hospital opened a general out-patient department last year, and a dental department will shortly be opened and a woman dentist appointed. Over 6,000 out-patients are on the books, and the Committee have already collected £4,000 towards the building fund.

Special Insurance Act Inquiry.

In view of complaints as to the medical attendance and treatment for insured persons, the Association of Approved Societies, which represents a membership of over four millions, has recently appointed a special committee, under the chairmanship of the Earl of Lytton, to conduct an investigation into the whole subject, with a view to publishing a comprehensive report early in the New Year. The committee is sending a letter to panel doctors, medical officers of health, insurance committees, approved societies, hospitals, charitable institutions, and other quarters interested, containing over 100 questions. It is understood that the Government intend to introduce an Insurance Act Amendment Bill early next session, dealing with the position of the deposit contributors.

School Dental Clinics—Announcement by Nationa Board.

The Commissioners of National Education desire to call the attention of managers and teachers of National Schools to the facilities which are now afforded by their regulations for the dental treatment of school children. Schemes for the dental examination and treatment of pupils may be submitted to the Commissioners, who are prepared to contribute half the cost of the necessary clinical equipment and half the cost of the treatment within certain limits. A successful beginning has been made already in different districts throughout the country by the inspection and treatment of the teeth of the children of the National Schools, but as the Commissioners have considerable funds still at their command for the purpose, they would wish to see a much wider extension of the provision. They are anxious that all persons interested in the National Schools, and especially the teachers, should endeavour to give effect to their wishes, and that as much as possible of the funds at their disposal for dental treatment during the current financial year should be utilised before March 31st, 1914. National teachers are reminded that under Rule 128 (e), the minimum time constituting an attendance may include any time occupied by visits to dental clinics during school hours. In the absence of a general scheme of medical inspection which the Commissioners would desire to see established, the care of the teeth of the children is an essential of all school hygiene.

King Edward's Hospital Fund for London.

A meeting of the Governors and General Council of King Edward's Hospital Fund for London for the purpose of awarding grants to the hospitals, convalescent homes, and consumption sanatoria for the present year, was held last week at St. James's Palace. It was announced that the Fund would benefit by about £465,000 in all under the will of Sir Julius Wernher; also that the difference with St. George's Hospital had been settled.

The Royal College of Surgeons of England.

The following candidates have been admitted Fellows of the College:—

C. W. Archer, M.A., L.R.C.P.Lond., M. Bates, B.A., M.B.Oxford, F. G. Bell, M.D.Edin., T. H. C. Benians, L.R.C.P.Lond., S. E. V. Brown, M.B. Otago, G. H. Chisnall, M.B.Lond., T. B. Davis, M.D. and M.R.C.P.Lond., F. H. Diggle, M.B. Manch, N. Duggan, M.B.Manch., P. J. Franklin, L.R.C.P.Lond., J. S. Jobson, B.A., M.B.Camb., N. C. Lake, M.D.Lond., A. L. Moreton, M.B.Lond., J. T. Morrison, M.B.Edin., C. T. Neve, M.B.Lond., S. B. Radley, M.B.Lond., E. H. Rainey L.R.C.P. Lond., R. A. Ramsay, B.C.Camb., L.R.C.P.Lond., E. Rayner, M.B. Camb., J. L. Ritchie, Lieut. R.A.M.C., M.B.Birm., R. M. Rowe, M.A., M.D.Edin., E. G. Schlesinger, M.B.Lond., W. A. Sneath, M.B. Manch.

The following candidates who are not Members of the College have been also admitted Fellows:—

J. S. Bookless, M.B.Lond., A. Gibson, M.B.Edin., J. Gow, M.B.Manch., R. C. MacQueen, M.B.Edin., J. C. Stewart, M.S., M.D.Durham.

The following candidates have been admitted Licentiates in Dental Surgery:—

L. Alabone, H. J. F. Alexander, R. H. Basker, F. E. Bendix, C. G. Bowen, R. G. Bradley, A. A. Brown, W. A. Bulleid, A. F. Camp, J. P. Cocker, L. C. Cohen, R. G. Cowell, F. A. Craine, W. A. Crane, E. Dinsmore, C. H. Edwards, P. W. Flook, W. T. Flooks, W. K. Fry, M.R.C.S., V. A. F. Greenish, F. C. Harrison, C. J. O. Jensen, E. E. Johnson, W. S. Johnstone, N. H. Kettlewell, S. McCallin, P. S. McFarlane, W. R. Matthews, L. T. Montgomery, N. Mulliner, C. H. Oliver, J. S. Palmer, H. Peters, K. C. Pitman, F. R. Rice, R. H. Rix, G. H. H. Russell, G. V. Saunders, F. S. Simpson, H. L. Smith, R. C. W. Staley, T. W. Stark, S. Stevens, E. W. Thomas, H. Treleven, A. B. G. Underwood, M.R.C.S.Eng., R. McKenzie Veale, G. H. Warner, G. L. Wilkinson, M. L. Williams, H. V. Wolfenden, H. Wolff, P. B. Wood, L. D. Wright, M.R.C.S.

The following candidates have been admitted Members of the College:—

A. S. Cohen, and T. O. Shah.

University of Oxford.

In a congregation held on December 13th, the following degrees were conferred:—

D.M.—E. P. Poulton, Balliol; M. B. Baines, Exeter; A. J. Jex-Blake, Magdalen.

B.M.—J. A. G. Sparrow and A. H. Southam, Christ Church; R. O. Ward, Queen's; G. T. Herbert, Christ Church; J. F. Venables, Magdalen.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Dr. T. S. (Beds).—The Plunket Society of New Zealand is, so far as we are informed, a society for educating the upper classes in the methods for the prevention of infant mortality. It is stated that there are now 70 branches of the society covering an extent of 1,000 miles.

NOT THAT!

Lecturing the other day under the auspices of the National Health Society on health, fatigue, and repose, Professor Stirling incidentally referred to what he called sermon-time somnolence.

If we snooze in church 'tis because we're tired—
  Because the air is a trifle hot—
Because there's a somnolent feeling round,
  Or the building's ventilated not—
Because, perhaps, we are sitting still
  (Oh for a friendly nudge or shake)—
Because (humanity's so perverse)
  One ought, of course, to be wide awake—
Because the day is a day of rest
  (After the week a welcome lull),
And many another reason why;
  But never because the discourse is dull.

The Western Mail.

A. L. O. A. (London).—The subject is not of sufficient interest to our readers to warrant insertion in the present exceptional demand on our space.

M.B. (South Hackney).—We cannot trace the original paper to which our correspondent refers. A comprehensive article on cardiovascular symptoms and their treatment in diabetic coma appeared in the *Berlin Klin. Woch.*, No. 31, pp. 1421-1464 (1913).

Meetings of the Societies, Lectures, &c.

Wednesday, December 17th.

Royal Society of Medicine (Section of the History of Medicine) (1 Wimpole Street, W.).—5 p.m.: Lecture: Professor Richard Caton: Health Temples in Ancient Greece and the Work carried on in Them. Illustrated by the epidiascope. (All members of the Medical Profession, including Students, whether Fellows of the Society or not, are invited to attend this meeting.)

British Oto-Laryngological Society (11 Chandos Street, Cavendish Square, W.).—4.30 p.m.: Meeting.

Royal Microscopical Society (20 Hanover Square, W.).—8 p.m.: Paper: Mr. C. Beck: The Binocular Microscopes of the Past and a New Form of the Instrument.

Thursday, December 18th.

Royal Society of Medicine (Section of Dermatology) (1 Wimpole Street, W.).—5 p.m.: Cases by Dr. G. Pernet, Dr. J. M. H. MacLeod, Dr. Knowsley Sibley, Dr. S. E. Dore, and others.

Friday, December 19th.

Royal Society of Medicine (Section of Electro-therapeutics) (1 Wimpole Street, W.).—8.30 p.m.: Paper: Dr. Max Heiner (of St. Joachimsthal Sanatorium): Modern Radium-Therapy in all its Branches.

Royal Society of Medicine (Section of Balneology and Climatology) (1 Wimpole Street, W.).—Members of this Section are specially invited to attend the Meeting of the Section of Electro-Therapeutics.

Society of Tropical Medicine and Hygiene (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Paper: Dr. C. M. Wenyon: Kala-Azar in Malta, with some Remarks on the Various Leishmaniases. Demonstration: Dr. H. B. Fantham and Dr. J. G. Thomson: Cultures of Piroplasma Canis. Malarial Culture Specimens: Dr. D. Thomson. Paper: Dr. J. O. Shircore and Mr. P. H. Ross: Epidemic Cerebro-spinal Meningitis in Nairobi.

Appointments.

Fairbank, H. A. T., M.S.Lond., F.R.C.S.Eng., Surgeon to In-patients at the Hospital for Sick Children, Great Ormond Street.

James, W. Warwick, F.R.C.S.Eng., L.D.S., Assistant Dental Surgeon to the Middlesex Hospital.

McLean, Alex. G., M.B., Ch.B.Aberd., House Physician at the West End Hospital for Diseases of the Nervous System.

Rivera, F. E., M.R.C.S., L.R.C.P.Lond., House Surgeon at the Eye Hospital, Oxford.

Robertson, W. A., M.B., Ch.B.Edin., Honorary Surgeon to the Hartlepools Hospital.

Vacancies.

Oxford County Asylum, Littlemore, near Oxford.—Assistant Medical Officer. Salary £200 per annum, with apartments, board, and washing. Applications to the Medical Superintendent.

Joint Counties Asylum, Carmarthen, South Wales.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to the Medical Superintendent, Asylum, Maidstone.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent

Nottingham General Dispensary.—Resident Surgeon. Salary £220 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

Corporation of Birmingham.—City Hospital, Lodge Road.—Assistant Resident Medical Officer. Salary £150 per annum, with board, residence, etc. Applications to the Medical Superintendent.

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Kidsgrove (Stafford), Redhill (Surrey), Blairgowrie (Perthshire), Moville (Co. Donegal), Newbury (Berkshire).

Births.

Maguire.—On December 13th, at Fulwood, Kew Gardens, to Dr. and Mrs. Maguire—a son.

May.—On December 4th, at Karrageen, Marlborough, S. Devon, to Dr. H. and Mrs. O'Hara May—a daughter.

Mayou.—On December 11th, at 51, New Cavendish Street, London, the wife of M. S. Mayou, F.R.C.S., of a daughter.

Odell.—On December 14th, at "Ferndale," Torquay, the wife of William Odell, M.D., F.R.C.S., of a son.

Wood-Hill.—On December 6th, at Staithe House, Beccles, to Dr. and Mrs. Wood-Hill—a daughter.

Marriages.

Ashley—Lavington.—On December 11th, at the Cathedral, Brisbane, Thomas E. Ashley, M.R.C.S., L.R.C.P.Lond., of Brisbane, second son of R. W. Ashley, Esq., J.P., and Mrs. Ashley, of Woodville, Stoke Bishop, Bristol, to Muriel, second daughter of Mr. and Mrs. Cyril E. Lavington, of Druid Stoke, Stoke Bishop, Bristol. (By cable.)

Crabb—Newnham.—On December 11th, at Holy Trinity, Dorchester, Robert Lawson Crabb, M.D., B.S.(Lond.), of "Strathfinta," Esher, Surrey, son of James Crabb, M.A., M.D., of "Craigilea," Parkhurst Road, N., to Alice Muriel, elder daughter of Mr. and Mrs. H. S. Newnham, of Rodlands, Dorchester.

Fairbairn—Stuart.—On December 9th, at St. Simon Zelotes, S.W., John Shields Fairbairn, M.B., F.R.C.P., F.R.C.S., of 42, Wimpole Street, W., to Elma, second daughter of the late J. P. Stuart, of Clanallan, Elgin, N.B.

Tatchell—Fraser.—On November 29th, at St. Paul's Westbourne Grove, Percy Tatchell, M.R.C.S., L.R.C.P., youngest son of Edward Robert Tatchell, and of the late Mrs. Tatchell, of North Bank, Sea View, Isle of Wight, and 73, Holland Park, W., to Miriam, youngest daughter of the late James Fraser, of Lloyds, and of Mrs. Fraser, of 16 Prince Edward Mansions, W., and Craighill, Kessock.

Ticehurst—Cross.—On December 8th, at St. Alphege, Greenwich, Norman F. Ticehurst, M.A., M.B., B.C., F.R.C.S., eldest son of A. R. Ticehurst, J.P., of Huntbourne, St. Michael's, Kent, to Ivy, second daughter of Henry Cross, of Greenwich, and granddaughter of the late G. R. Cross, Sen., of Taplow, Bucks.

Deaths.

Footner.—On December 11th, at Westcliff-on-Sea., Edward Footner, M.D., Brigade Surgeon, of 8, Hanover Terrace, W., second son of the late G. B. Footner, solicitor, Romsey, Hants.

Landon.—On December 7th, at 169 High Street, Homerton, N.E., Edward Landon, M.R.C.S.Eng., L.R.C.P.Edin., late Captain R.A.M.C., aged 58.

Skelton.—On December 8th, at his residence, Overnhill, Downend, near Bristol, Henry Skelton, M.D., M.R.C.S., M.R.C.P., aged 71.

Woods.—On December 10th, at Dashwood House, Ramsgate, from septic poisoning, Frank Woods, M.R.C.S., L.R.C.P., L.S.A.

Young.—On December 10th, at 122 Herrington Street, Sunderland, Thomas Beveridge Young, L.R.C.P. and S.Edin., L.F.P.S.Glasg., aged 44.

Macartney.—On December 6th, at Cinderford, Richard Macartney, L.R.C.P. and S.Edin., L.M., aged 52.

Duke.—On December 7th, at Cheltenham, Allen Forrester Duke, L.R.C.P.Edin., and L.M., aged 50.

Keith.—On December 4th, suddenly, at Heolycyw, Dr. W. G. Neill Keith, aged 48.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, DECEMBER 24, 1913. No. 26.

NOTES AND COMMENTS.

Admission Diagnosis.

IN spite of the general excellence of administration of our great voluntary hospitals, we are reminded from time to time that there is still room for improvement. It sometimes happens, for instance, that a patient is refused admission and sent away with some critical or mortal condition unrecognised. Last week a London inquest disclosed an unfortunate incident of the kind at the new King's College Hospital, Denmark Hill. A mother took a five-weeks old baby to that institution, and, according to her statement, was told by the porter to bring the child at some day later. She was later sent to the casulty ward, where another porter told her to bring the baby on a particular day (Friday). The child had developed a skin rash, and was admitted eventually at the Evelina Children's Hospital, where it died two hours after admission. The jury returned a verdict of death from natural causes, and added a rider that they were dissatisfied with the conduct of the hospital porter. If the facts be as stated in the newspaper reports, their dissatisfaction is likely to be shared by a number of other people. It seems incredible that at any great hospital the highly skilled and responsible duty of admitting or sending away applicants should be relegated to a porter. Nor can it be believed that any such method is sanctioned at King's College Hospital. At the same time it seems clear that there is some little laxity in management, otherwise an accident of the kind under notice could hardly have occurred. In most large general hospitals, London or provincial, there is room for a good businesslike department, properly staffed, for the rapid, careful, and systematic examination of all applicants. One great source of trouble is an overworked and under-manned resident medical staff.

A Dental Students' Strike.

A GENERAL strike has recently taken place amongst the students of dental surgery at Berlin, Munich, Leipzig, and some half-dozen other universities. Their grievance was that the academically-trained student, so far as the public was concerned, was indistinguishable from the practitioner who had undergone merely a technical training as an apprentice. It appears that recently the non-academic dentists have been admitted to State Insurance practice, and are to be given a kind of official certificate of efficiency. In order to distinguish the university-trained dental surgeon, who has to undergo a prolonged training and pass three examinations, the academic students demand the institution of a new degree, namely, that of "Doctor of Dental Surgery." The strikers refused to attend lectures until the authorities agreed to give careful consideration to their demand. At Freiburg, the Faculty of Medicine has promised to communicate with the Government in support of their demand, and the Prussian Chamber of Dentists has consented to reconsider the question. The students certainly appear to have justice on their side, for if the State has recognised the necessity of a legal examination and qualification in dentistry, surely it should not admit to dental practice persons who have not submitted to a similar course of training and of examination tests of proficiency. A dental surgeon must attain a certain scientific standard of knowledge, and the State cannot consistently recognise untrained dentists as being in the same category.

Our Own Untrained Dentists.

THE situation finds a kind of echo in the United Kingdom. The State has instituted a curriculum and examinations for good standard of legal dental qualification. On the other hand, it offers no obstacle whatever to any ignorant person who may choose to set up in practice as a dentist. The result is that tens of thousands of unqualified persons compete with the orthodox dental surgeon who has acquired his credentials from the State at a considerable expenditure of time, labour and money. The situation is farcical. The obvious underlying reason that prompted the State in insisting upon the adequate scientific training of dentists is the protection of the public. What greater failure could there be than that of a system which permits Dick, Tom and Harry to fit up a surgery and workshop and set up as practising dentists? Possibly the scope of the Royal Commission into patent medicines and unqualified practice might include irregular dentistry. The Commission, however, has fallen flat, and from the first it was predicted in some quarters that no other result was looked for officially. So the dental question will probably have to wait a few more generations for settlement, like the older problem of medical quacks and quackery.

Bengal Excise Folly.

THE Bengal Excise has recently performed a feat of more than usual stupidity, even for Indian officialdom. India has very properly determined to root out, as far as possible, the pernicious cocaine habit, which has taken a firm hold of her people. To that end the Excise have been exercising the greatest vigilance both over shipping and over the town of Calcutta itself. As the result of this activity some £25,000 worth of cocaine was seized, and, incredible as it seems, the whole lot was forthwith thrown into the river Hoogley. This fatuous and wanton destruction reminds one of the silly way in which contraband tobacco was burnt in London in a furnace known popularly as the "King's Tobacco Pipe." All tobacco now seized by the British Customs is bestowed in useful directions—such as naval hospitals, and so on. Why should not the Bengal Excise follow a sensible example of that kind? Cocaine is small in bulk, and the whole £25,000 worth could have been sent from Bengal to London Dock at a trifling cost. Here, in England, it would have been used for legitimate drug purposes. It might, for instance, have been handed over to Mr. Winston Churchill, with a view of somewhat reducing the inordinate naval expenditure. The richest empire in the world cannot afford to throw away wealth in the reckless fashion adopted by the Bengal Excise. It is to be hoped the Indian Government will take steps to put an end to such stupidity.

Surgical Operations and the Children's Act.

The frequency of the occurrence of such abnormalities as adenoids and enlarged tonsils in children has been made more apparent of late years since the introduction of the system of school medical inspection. Many of the defects so discovered are capable of being remedied by very simple operations. The removal of vegetative growths in the naso-pharynx, as every medical man knows, results in nothing but good to the child. The airway is cleared, respiration becomes freer, the blood is thereby better aerated, and a host of troublesome minor reflex phenomena disappear shortly after the little operation, to say nothing of the improvement in the mental condition resulting from the relief of the deafness. Only a short time ago it was decided in the High Court by Mr. Justice Darling that a parent, who refused to allow an operation on his child for adenoids, if considered necessary for health reasons by a medical man, was guilty of "culpable neglect," within the meaning of the Children's Act. Such a side issue as the possible co-existence of the condition known as status lymphaticus should not be allowed to question the wisdom of such a decision, for no one except a medical man can form any judgment as to the advisability or otherwise of operation, not only in cases of adenoids, but in all morbid conditions of childhood capable of being relieved by surgery. In doubtful cases where an operation may or may not do good, the parents may rightly be given the final choice, but where it has been shown that operative interference is the best form of treatment, then the decision should rest with the medical man, and failure to comply with this should constitute negligence under the Act.

Patients of Moderate Means.

Last week a new nursing home was opened in London, under the name of the Empire Hospital, for paying patients. It is an up-to-date, modern building, fitted with operating theatre, X-ray installation, various kinds of baths, and so on. The hospital, so it is announced, is designed for the reception of persons of moderate means who cannot afford to enter an expensive nursing home, but who do not feel justified in accepting the charity of the free institutions. The terms on which patients are admitted range from £3 to £10 per week, a fact that leads one to speculate on the definition of "moderate means" as it appears to the directors of this strictly businesslike venture. There is no pretence at philanthropy about the affair. The chief way in which this "hospital" differs from Guy's and St. Thomas's and other voluntary hospitals that receive paying patients is that the latter are using money subscribed for the benefit of the poor, and any profits go to the common fund of the charity. The Empire Hospital, on the other hand, is frankly commercial. So far as the medical profession is concerned, it does not enter into competition with them by appointing its own medical staff, but any medical man may attend his own patient, which is not the case in the voluntary pay wards. From a legal point of view it may be questioned whether the voluntary hospitals are not grossly violating the terms of their charters in what amounts to trading upon charitable funds. The Empire Hospital should be useful as a check on the exorbitant charges of many private nursing homes—but we imagine there is still room for a large lower-middle-class nursing pay hospital.

Third Party Examination.

Many riskss of unfounded charges of misconduct are inherent to the medical profession. Some are due to the baser motives, such as blackmailing or revenge, some to insane delusions, others to sheer credulity and lack of mental and intellectual balance. As a matter of fact, a certain number of these unpleasant episodes might be avoided by the exercise of a few simple precautions on the part of medical men. Let us take the point of the vaginal examination of young unmarried women, a proceeding out of which arise not a few of the serious charges brought against medical attendants. It is obvious that now and then such an examination may be absolutely necessary in the interests of the patient herself, inasmuch as it is essential to the formation of a correct diagnosis. Rarely, however, could the urgency of such investigation be so great as to prevent the possibility of securing the presence of a nurse or other female. The golden rule in this case would be, never examine *per vaginam* an unmarried woman except in the presence of a third party, and as far as possible extend the rule to all examinations of the kind even in the case of married women. Many blackmailing attempts would have been foiled at once by the adoption of some such plan. In the medical, as in other callings, to be forewarned is often to be forearmed.

LEADING ARTICLES.

THE KING EDWARD FUND AND THE SMALL HOSPITALS.

That the King Edward Fund is a noble institution goes without saying. It has secured for London a vast endowment for its voluntary medical charities. Money has flowed into the coffers of the great distributing agency founded by our late King like the proverbial water. On the authority of a leading hospital journal we learn that during the sixteen years of its existence the Fund has raised and distributed directly amongst the hospitals and convalescent homes upwards of one million and three-quarters sterling. This is an achievement of which any nation might be proud; and it is in no carping spirit that we once again call attention to what has always seemed to us to constitute a serious defect in the policy of the Fund—namely, its neglect of the small hospitals.

A few special institutions have been favoured with grants, some of them of large amount, but the general attitude of the King Edward and of the Sunday Funds has been one of absolute denial of recognition of the bulk of the smaller hospitals in any shape or form. It is difficult to think that those who gave their money to the King Edward Fund could have anticipated such a curtailment of its distribution. Of all the vast amount of relief to the suffering poor that is performed, year in and year out, by the London medical charities, a not inconsiderable portion is carried out in the smaller institutions. It would be nothing short of a calamity not only to the sick persons of the hospital class, but also to medical science, were the doors of those institutions to be closed. There is probably no finer scientific work done in the whole wide world than that carried on unostentatiously day by day in the special hospitals of London. Why, then, should they be deprived of a fair share of the money given by wealthy philanthropists for the support of the medical charities of London? The injustice to the donors inflicted by the exclusion of the smaller institutions could be swept away by a stroke of the pen. It probably arises, in the first place, from the fact that the King Edward Fund is governed by a non-representative body, on which are many members directly interested in the large hospitals. Within the last year or two some improvement has taken place in both the Funds under discussion with regard to the special hospitals. Many small and struggling institutions, nevertheless, are absolutely ignored. Even the lately instituted Alexandra Day Fund has adopted the same policy, and has given much to those that already have much, while the poor have gone empty away. Last year King George sent presents of game to some of the small hospitals that had never before been recognised by members of the Royal Family. It was hoped—and, indeed, believed in some instances—that this was a sign of better things to follow from the Fund which owes its origin to the late King Edward. Perhaps in the coming year it is not too much to hope that a few of its overflowing thousands may reach the smaller hospitals, whose resources have been taxed to the uttermost by the incidence of the National Insurance Act. Could the history of the special hospitals be revealed, in spite of all defects, the picture as a whole would be one of noble self-sacrifice and of duty nobly done in the face of many adversities.

CURRENT TOPICS.

The National Medical Guild.

At a meeting of the National Guild held at the Hammersmith Town Hall, on December 19th last, the policy of that body was clearly defined. Dr. Buttar, who presided, explained that the Guild was registered as a friendly society. In face of the collapse of the British Medical Association's fighting fund, he emphasised the importance of their own scheme. Mr. E. B. Turner dwelt on the value of a friendly society; its fighting fund would be on a safer basis. Then there was the possibility of representation in Parliament. He insisted upon the desirability of working harmoniously with the British Medical Association, a body that, from a legal point of view, it was practically impossible to form into a trade union. Dr. Percy Raiment, the general secretary, followed on the same lines, and gave an encouraging report of the growth of the Guild, with a rapidly increasing membership in the branches at Sheffield, Leeds, Manchester, Oldham, Rochdale, Plymouth, South Wales, Forest of Dean and various places along the South Coast. He claimed superiority for the Guild's method of forming a fighting fund —namely, that of making levies upon members when required, with the restriction that the amount thus levied should not exceed a certain maximum in any one year. A full report of this important movement will be found elsewhere in our columns.

Tuberculosis in England and Wales.

The tuberculosis returns show a formidable amount of the disease in England and Wales. Notification has naturally led to the disclosure of a large number of cases, the existence of which formerly could only be estimated roughly by a consideration of the mortality returns. During the year 1912 a total of 110,708 cases of pulmonary tuberculosis were notified in England and Wales, and of these no less than 33,392 were in London. So far as actual deaths were concerned, in England and Wales there were in 1911 (the latest year for which returns are available) 39,232 from pulmonary and 13,888 from other forms of tuberculosis. These figures show the magnitude of the task that lies before the sanatoria in ridding the State of this particular pestilence. They emphasise, moreover, the necessity of some comprehensive system—such as that provided by the National Insurance Act—for special sanatoria in which sufferers from the malady in an active form may be segregated. From an economic point of view, the loss to the community from this disease is enormous. It means that many valuable lives are lost. Many years of productive labour are lost; and the burden of the support of many invalids is cast upon the community. Now that some sort of control is exercised over tuberculous meat and milk, there is a reasonable prospect that the scientific preventive measures now adopted in the case of human tuberculosis may result in the practical extermination of the latter within the present generation. Much remains to be done, however, before that happy consummation is attained.

Medicine in Ancient Greece.

In lecturing before the Section of the History of Medicine of the Royal Society of Medicine last week on "Health Temples in Greece and the work carried on in them," Dr. R. Caton, of Liverpool, referred to the value of recent excavations in the region of Athens whereby the precinct of Amynos has been laid bare. It seems likely that both in medical lore and also in the superstition accompanying it, Greece was behind Egypt. Numerous minor deities or deified men appear to have taken the place of Apollo as healers and protectors of the sick. The inscriptions upon portions of the temple of Amphiaraos, near Oropus, in Attica, show that this sanctuary was founded in the fifth century, and that it was closed during the winter. The greatest centre of healing appears to have been that of Epidaurus, where there flourished a temple famous for its architectural features. On arrival at such a temple the patient would undergo ceremonial purification, including the payment of necessary fees, and on entering the Tholos he would offer bloodless sacrifice to the snakes, feeding them with honey cakes. He would bathe in the sacred fountain and offer sacrifices, while priests and physicians probably arranged diet and treatment. At night he would enter the Abaton with his bedclothing, and repose on one of the couches. At nightfall, when the lamps had been lit, the priest would enter and recite the evening prayers to the god. Silence would then be enjoined, the lights would be put out, and the priest would command all to fall asleep and hope for guiding visions from the god. As time went on superstition had a less share, and science a greater one, in the work of healing. The priest prescribed diet of a plain and simple kind, hot and cold baths, poultices, various medicaments such as hemlock juice, oxide of iron, hellebore, squills, lime water, drugs to allay pain, active gymnastic exercise, friction of the skin, counter-irritation, and bleeding; surgery also was practised. Apart from the cruel superstition which allowed neither birth nor death to take place in the holy precinct, the sick appeared to have been treated with kindliness and humanity, and were in general greatly benefited. The whole atmosphere of the place was helpful. The patients could sit and rest in the semi-circular seats provided while the more cultured occupied themselves in reading books from the library. The study of the innumerable votive offerings and commemorative tablets recording cures must have excited a beneficial faith and hope. The pure air of the mountains by night and day, the plain, simple diet, the rest and change, the medical treatment, and the beauty and charm of the place made Epidaurus intensely popular among the Greeks, and the early Christian teachers found it more difficult to displace Asclepios than any other of the gods of Greece or Rome from the beliefs of their converts. Thus were many of the cults of the present day foreshadowed, and no doubt many real cures were obtained.

The Taxi Habit.

Man is the creature of habit, especially when it comes to riding in "Taxis." Life is nowadays so full of hurry and jostle that rapid locomotion alone enables the average townsman to keep pace with its myriad activities. To the busy citizen, whether on pleasure or on business bent, the "taxi" comes as a boon and a blessing, by the help of which he may fulfil an ever-increasing crowd of engagements. What matters it to him that he is thereby hastening on the process of evolution that is developing the brainy side of man at the expense of his body? For every increased facility of mechanical locomotion means a corresponding decrease of muscular exertion. In a word, man is more or less within sight of the time when he will to a great extent abandon the use of his lower limbs, which, later, will atrophy and dwindle into mere relics of the handsome members they now are. This picture is not altogether fanciful, for some of the North American Indian tribes have ridden on horseback for so many generations that they become awkward and defenceless when compelled to go afoot. With all this in mind the man in the street will do well to walk instead of jumping into a taxi. There are other aspects of the case which appertain to the province of the economist rather than to that of a medical journal. The cost of incessant taxi travelling, for instance, drains away money that might be more profitably spent in food, clothes, recreation and other useful directions. Then there is the taxi "tip"—but that we do not propose to discuss at length. It is curious how a respectable and capable set of men like the modern chaffeurs can submit to conditions of employment which render them subject to so humiliating a species of remuneration as that of passengers' gratuities. This question is merged in the greater problem of how far any man is entitled to look for extra pay for discharging his bounden duty. It is the middleman cab-owner who is responsible for shifting part payment of the chauffeur's wages to the shoulders of the taxi-riding public.

The New Beit Fellows.

The results of the fifth election to Beit Fellowships for Medical Research were made known last week. From among 35 candidates the following have been chosen:—Dr. J. O. W. Barratt, Director of the Cancer Research Laboratory, Liverpool University, who at the Lister Institute will study the nature and mode of action of substances contained in or derived from blood plasma; and also cytological studies. Dr. M. Coplans, Demonstrator in Bacteriology and Public Health at Leeds University, who at the Lister Institute will study immunity, with special reference to the action of the silicates upon bacterial and allied substances. Mr. E. C. Grey, at present engaged in research work at the Kaiser Wilhelm Institute in Berlin, who at the Lister Institute will study bacteriological chemistry, with special reference to the relation between bacterial enzymes and chemical configuration. Dr. J. R. Marrack, who is at present engaged in research work at the Cambridge Hospital, and will there study the chemical pathology of arthritic diseases. Dr. V. H. K. Moorhouse, of the Washington University School, St. Louis, who at University College, London, will investigate the metabolism of animals, with special reference to the question of diabetes. Dr. G. E. Nicholls, Professor of Biology at Agra College, India, who at King's College, London, will continue research investigations on the structure and function of the subcommissural organ and Reissner's fibre. Dr. Annie Porter, at present engaged in research work in parasitology at Cambridge University, who will study parasitic entozoa at Cambridge and elsewhere. Dr. J. G. Priestley, of St. Bartholomew's Hospital, who, at Oxford, will investigate the factors concerned in the regulation of the excretion of urine. Dr. Jane Isabel Robertson, the holder of the Carnegie Research Fellowship, engaged in work on the comparative anatomy of the vertebrate heart, who will continue that work at the Victoria Infirmary, Glasgow. Miss Margery Stephenson, who is engaged in research work in London University College, and will there investigate the metabolism of fats. Dr. J. G. Thomson, of the Liverpool School of Tropical Medicine, who at the Lister Institute will investigate the cultivation of protozoa and of tumour tissues. The progress of scientific medicine should be considerably advanced as a result of the researches of these eleven new Fellows.

Novel Pathology.

The medical lore of the average novelist is inextensive but peculiar, and, as a sample of the lay notion of disease, interesting. The literary liabilities to physical disaster are limited. Humanity in novels is heir to few ills, and they are dramatic in incidence and strictly decent in description. This is as it should be. The novelist introduces disease only as a last resort. If wholesale death is to be dealt out, an earthquake, a shipwreck, or other "act of God," suffices. The retail removal of an individual calls for pathological selection. The Victorians liked tuberculosis; the fatal dark-lashed beauty associated with Koch's bacillus appealed to the followers of Byron. The interesting invalid, supported only by the *spes phthisica*, became the heroine of an age assuming decadence. We have left that now. The sharp snap of sudden death is what the writer wants. An eclectic aorta supplies him with potential destruction available at any time. He calls it heart disease. Physicians know that the mitral valve is occasionally diseased. The novelist prefers inquests and the aorta. "Brain fever" is a literary fiction of convenience. It lays the hero low for any suitable time in any suitable degree of moribundity. He invariably recovers amid the acclamations of a tenantry whose loyalty is obviously pre-Lloyd Georgian, often by the operation of "trepanning." "Trepanning" can do anything. The blind see, the deaf hear, the halt are made whole through its beneficent polyvalent manifestations. And pity 'tis 'tis not true. But altruism can go too far. Doctors must live, and in the paper world they are of little use. They may dash down and operate, but for the rest, therapeusis is left in the gentle hands of the entirely successful but pointedly untrained flapper, whose fate we have diagnosed since the first chapter, and which the author commits to paper on the last page but one.

Pathology as Professional Work.

Up to the present we have regarded the practice of clinical pathology as a branch of medical professional work. There are very sound reasons why it should be so, and for preventing this branch of scientific work getting into the hands of persons of whose competence we have no guarantee. No decision in the practice of medicine demands greater responsibility than that as to whether, let us say, a particular piece of tissue is malignant or a particular specimen of blood gives evidence of syphilis. Yet it is a curious fact that in a great many cases medical men show the greatest indifference in obtaining decisions on such points. A practitioner is, as a rule, meticulously careful in his selection of a consultant that he may choose the man who, by experience and learning, is most fitted to help him in his difficulty. The same practitioner, however, is content to accept ready-made diagnoses from any so-called "research laboratory" without taking the slightest trouble to discover whether the person who is to decide some question of the utmost importance to his patient is possessed of either competence or skill. We have heard one physician in large practice boast that he was entirely guided in his choice of a laboratory by the amount of the fee. He sent his specimens to an unknown laboratory three hundred miles away because the fees charged were somewhat lower than those expected by pathologists of repute in his own neighbourhood. Yet no man would have been more careful in his choice of a surgeon to operate on one of his patients. It is to this kind of culpable carelessness that the growth of research laboratories run as side-shows by trading firms is due. Many of these concerns offer to perform difficult and intricate examinations for fees which could not remunerate competent men. The connection of qualified medical men with these advertising firms—if, indeed, they employ medical men at all—calls for the careful consideration of the medical profession. If it is contrary to medical ethics to advertise one's fees for amputating a limb or a breast, it would seen to be equally improper to advertise one's fees for examining sputum or performing the Wassermann test on blood.

PERSONAL.

Mr. Harold Black, M.B., D.P.H., has been appointed Radiographer to the Queen's Hospital, Birmingham.

Dr. E. B. Sherlock, M.D., B.Sc.Lond., D.P.H., has been appointed Medical Superintendent of Darenth Industrial Colony.

Major M. H. Babington, R.A.M.C., has been appointed Clinical Pathologist at the Queen Alexandra Military Hospital, London.

Mr. A. E. Mortimer-Woolf, B.A., M.B., B.C., F.R.C.S., has been appointed demonstrator in the Department of Anatomy at King's College.

Col. J. J. Pratt, I.M.S., F.R.C.S., has been appointed Surgeon to the Seamen's Hospital Society (Dreadnought), with duties at the Albert Dock Hospital.

An interesting lecture was delivered before the Guild of St. Luke last week by Dr. Graham Aspland on behalf of the medical work of the Society for the Propagation of the Gospel in China.

Dr. C. J. Alexander, of the Winsley Sanatorium, was the recipient the other day of a series of testimonials made on behalf of the matron and nursing staff, the servants and the patients, upon the occasion of his vacating the post of Resident Medical Officer at the institution.

Dr. and Mrs. W. W. Jones, of Gelligaer, were the recipients of a handsome testimonial the other day from the Gelligaer District Council as a token of the esteem in which they have been held for the last fifteen years, during which Dr. Jones was the Medical Officer to the Council.

It is announced that a dinner in honour of Dr. Christopher Addison, M.P., will be given on February 3rd, at which Mr. Lloyd George will preside. The acting secretaries are Sir John Collie, 25, Porchester-terrace, W.; and Dr. H. H. Mills, 21, St. Mary Abbot's Terrace, Kensington.

Mr. John Moore Walker, M.B., of Edgbaston, formerly Medical Officer to the Cheltenham Provident Dispensary, left net personalty £45,372. The testator left £13,500 in personal legacies, and the residue of his property to St. Bartholomew's Hospital which will apparently receive over £30,000.

We understand that Sir James Guthrie, President of the Royal Scottish Academy, has accepted the commission to paint the presentation portrait of Sir Robert Philip, M.D., F.R.C.P., of Edinburgh, and intends to commence work before the end of this year. The invitation to join in this presentation has met with a most cordial response, and the necessary amount has been subscribed.

Dr. J. A. Macdonald, M.D., LL.D., of Taunton, the Chairman of the Council of the British Medical Association, who has been chosen by that body to represent them at the Australasian Medical Congress to be held at Auckland, New Zealand, in February next, was entertained recently to dinner by the Executive Committee of the Taunton Conservative Association, of which he is president.

FRENCH CLINICAL LECTURE

ON

THE TREATMENT OF WOUNDS OF THE CHEST.

By D. SOULIGOUX, M.D.,

Surgeon to the Tenon Hospital, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

A CASUAL reader of the debates on the very present question of intervention in wounds of the chest might run away with the idea that surgeons were divided into two camps—the interventionists and the non-interventionists; but, in reality, there is not much difference of opinion. The most ardent interventionist does not advise interference as a matter of course; it comes to this—that in the immense majority of cases disinfection of the wound and the application of a dressing, followed by immobilisation of the patient, is all that is required. Nevertheless, there are cases in which the surgeon must abandon the expectant attitude and perform free thoracotomy and suture of the lung.

It must be admitted that no very precise indications are available, otherwise there would be no difference of opinion. In order to formulate the indications for operation cases of hæmothorax must be subdivided into four groups: (1) Where the hæmorrhage is at once very free and directly threatens life; (2) the effusion is considerable, but the surgeon hesitates; (3) the effusion which has remained at the same level during the first day is rapidly increasing and threatens life; (4) moderate effusion which does not tend to increase but shows no sign of a tendency to be absorbed.

(1) *The Hæmorrhage is such as to threaten life forthwith.*—These cases are not as rare as might be supposed from the infrequency with which they come to us, but as a rule too much time is wasted before they are taken to hospital so they die on the way. Lejars had a case of the kind. The patient was covered with blood, and blood was flowing from the wound in the precordial region; he was pale and pulseless, breathing being scarcely perceptible. M. Lejars operated at once and saved his patient. I do not suppose anyone would oppose intervention in such a case.

(2) *The General State is Grave and the Surgeon Hesitates.*—These are the cases in which it is most difficult to make up one's mind, and in which therefore there is most room for divergence of opinion. Death may be caused (i.) by loss of blood, (ii.) dyspnœa from pressure on the lung and heart. Our predecessors at the time of Ambroise Pare sought to avert these contingencies in two ways. Some dilated the wound instead of closing it, then placed the patient on the wounded side in order to promote the escape of blood from the pleura, and no doubt by this means the compression of the heart and lung is diminished, but the patient runs the risk of dying of loss of blood.

Struck by this fact, the surgeons of the following century made a point of closing the wound. No doubt this made for pleural effusion, but the accumulation of blood, by increasing intrathoracic pressure, was, *per se*, an excellent hæmostatic.

In presence of symptoms of suffocation threatening life, surgeons were led to practise puncture. This is what Nélaton did in a lad, æt. 18, withdrawing a couple of pints of blood, but the attacks of suffocation, relieved for the moment, soon returned and the patient died. M. Quenu related the other day before the Surgical Society how, after a first evacuation of 30 ozs. of blood by puncture and a further withdrawal of 8 ozs. he had, after all, been obliged to widely open the thoracic wall.

At the present time there is no fixed rule of conduct and surgeons are far from agreed as to what constitutes the best treatment of the class of cases under consideration. Some hold that an intervention is *de rigueur* without even waiting for any indications. Others, like Professor Zeidler, go still further. He and Stukey preach that every wound of the thorax of not more than twelve hours standing demands an operation, not of disinfection but of exploration. He argues that in presence of subcutaneous emphysema, which is of common occurrence, it is hardly possible to make out the presence of an effusion of blood less than a pint in amount. Similarly, pneumothorax may be simulated by the diminution of respiration on the fixed side in consequence of pain. No doubt it is not a matter of indifference to provoke pneumothorax, but either it exists and is then rather favourable than otherwise, or it does not exist and it would be dangerous to wait for it in order to explore the wound on the supervention of signs of internal hæmorrhage. His plan is to open up the wound under an anæsthetic in the direction of its course and for its entire length. If the wound has penetrated he uses retractors to separate the edges of the pleural wound and looks whether there is blood in the wound. If not, or only a little, he merely sutures the wound. If there be much, on the contrary, he opens up the wound and looks for the bleeding vessel. The procedure is simple enough; it amounts to an exploratory thoracotomy, but this plan is uniformly rejected in France and even in Germany it has been sharply criticised by Bouchardt, who remarks that among the 25 cases of thoracotomy recorded by Stukey several presented no pulmonary lesions at all.

M. Delorme, who is one of the foremost advocates of intervention and one of the most cautious, has endeavoured to formulate rules for this intervention. He says:—

" (1) When a copious rapidly developed hæmothorax reaches up to, or near, the angle of the scapula, intervention is indicated in order to arrest the bleeding. (2) With hæmothorax to medium amount, with repeated hæmoptysis or free spitting of frothy blood, lasting for upwards of 24 or 36 hours, intervention is again called for. (3) With a medium hæmothorax and serious external hæmorrhage, traversing the dressing, &c.,

intervention is necessary. (4) Serious external hæmorrhage not arrested by occlusion requires the same treatment."

We may possibly concede the last two propositions, but the first two are open to discussion. Numerous are the cases in which the blood has reached the limits assigned by M. Delorme, cases, too, in which the hæmoptysis was free, yet which have recovered on expectant treatment. One man supports a hæmothorax with impunity which would threaten the life of another, and M. Baudet holds that more importance is to be attached to physiological than to purely physical signs. The pulse and breathing, he says, are all-important in this respect. "Increasing dyspnœa which is becoming worse minute by minute, recurring attacks of suffocation, these are signs of the utmost significance." Dyspnœa consequent upon pulmonary distress is manifested by frequent superficial movements of respiration, movements of the alæ nasi and some cyanosis of the face. It only allows of gasping, panting speech, is increased by effort, and is associated with oppression. It is not relieved by repose in presence of grave pulmonary lesions. On the contrary, it is more intense on the second examination, and simultaneously we get a thoracic constriction, pain, and more marked cyanosis of the face. The pulse a few hours after the accident, even with moderate hæmothorax, rarely exceeds 114 per minute, and is still fairly strong. If, in our half-hourly examinations, we find it progressively more rapid and weaker, the wound of the lung is grave. Some surgeons do not yield even to this group of physical and physiological signs and hold that abstention is less dangerous than intervention, but statistics show the gravity of methodical non-intervention. Nélaton's statistics give 44 deaths out of 94 cases, in 5 due to lesions of the intercostal and internal mammary arteries, in 4 to internal hæmorrhage, in 6 to lesions of the big vessels. At Strasburg, in 1870, out of 98 fatal cases, death was due to internal hæmorrhage in 24. Fischer admits 19 deaths out of 34 wounds. Garré gives a mortality of 40 per cent., and even since the introduction of antiseptic methods the mortality is not lower than 30 per cent.

M. de Martel has collected 42 cases of intervention with 28 recoveries and 14 deaths, *i.e.*, 33 per cent. Baudet's personal figures give a mortality of 25 per cent. But all these cases are not comparable. There were only 8 cases of true lung wound and these yielded 7 recoveries and one death under chloroform. As M. Rochard remarked at the Surgical Society, seeing that de Martel's statistics only bore on cases of the utmost gravity, that owing to defective *technique* in 16 cases they had to plug without being able to suture, we may conclude that in wounds of the lung accompanied by serious hæmorrhage, intervention is superior to abstention.

The objections to intervention are: that patients with chest wounds followed by grave hæmothorax recover better under complete immobilisation than after operation (which we have seen is not the case). They urge, moreover, that the operation entails free opening of the thorax, thus running the risk of converting a closed hæmothorax into an open one; that there is the risk of pleural infection; that in addition to post-operative shock the patient is exposed to the risk of infection. To my mind these criticisms are unfounded. The shock is not very great, and the operation was well borne by most of the victims. Penetration goes for little or nothing in respect of secondary infection. In most instances there is already air from the bronchi containing septic germs which, moreover, may have been introduced by the lethal weapon. Then, too, there are plenty of cases on record in which patients operated upon for copious hæmothorax have recovered after ligature or suture of the divided vessels without drainage. This goes to show that septic complications are not solely the consequence of the intervention, since they are common in non-operated patients.

As a matter of fact, what checks the surgeon is the difficulty of knowing whether the hæmothorax, which has attained a certain volume, is not going to stop spontaneously under the pressure of the blood in the pleura. If we wait too long the time for intervention goes by. M. Quénu in such cases recommends puncture with removal of part of the blood. If, then, the hæmothorax tends once again to increase, it is a sign that the hæmorrhage is persisting and we must intervene This is a practical suggestion, but the puncture must not be repeated or we shall bleed our patient to death.

In presence of a serious effusion of blood into the chest the proper course appears to me to be as follows: Examine the patient carefully to make out the extent of the hæmorrhage. I do not attach the importance that some do to moving these patients, for in any case they have been moved a good deal before they reach the hospital. No doubt, in cases where there are no symptoms pointing to the necessity for intervention, it is better to leave them absolutely at rest, but when we have to take a life and death decision I think we must neglect no possible means of diagnosis. Therefore, after complete examination of the patient, after taking into account the amount of the hæmothorax, the state of the pulse and the heart and the breathing, we must stay with the patient, having made everything ready for an operation under the strictest antiseptic conditions. If, an hour or two later, the pulse is not failing and the heart is not further displaced, we can wait, though still keeping him under close observation. If the contrary takes place, if the pulse becomes more rapid and weaker, if the dyspnœa increases and the heart is more and more displaced, then I think it is wise to adopt Quénu's plan and puncture in order to withdraw part of the blood. This gives immediate relief and if this be maintained well and good; otherwise we must intervene forthwith.

(3) *Cases in which the Effusion, after Remaining Stationary for the first 24 hours or for some days, is increasing and threatens life.* These may be divided into two categories. In one series the effusion which had remained moderate in amount during the first day is increasing and threatens life. In such a case, under Dr. Delbet, a young man was admitted with a wound of the left lung. His state did not appear grave, as there was only a little blood-stained expectoration. The wound was closed, and he was kept quiet. The next day there was a tangible amount of effusion, and on the day following this had increased. His general state, however, seemed satisfactory, and there was very little dyspnœa, so that no intervention was thought of, yet the patient died during the night. This case shows how necessary it is to keep these patients under observation, and proves that when

the lung is going on bleeding the patient is in danger and an operation is called for. In these persistent hæmorrhages the displacement of the heart takes place slowly and the consequent dyspnœa is not very marked.

In a second category the effusion, after remaining stationary for several days, begins to increase. This may be due to two causes : (1) The obstruction clot may have become detached, and it is a case of secondary hæmorrhage ; or (2) there is effusion of serum. In the former case thoracotomy must be performed. The effused blood is readily and rapidly absorbed in the absence of infection. The latter may attack the pleura directly or involve it secondarily *via* the lung, which develops traumatic pneumonia. In short, hæmothorax is often complicated by serum exudation, deeply stained red, so much so as to resemble pure blood.

In this event, the temperature may run high as the result either of the traumatic pneumonia or the pleural reaction. The fever, *per se*, does not constitute an indication for operation. There are plenty of cases on record to show that hæmothorax, complicated with fever or not, is capable of undergoing fairly rapid absorption. In my opinion, however, this is not the question. What we want are indications for our guidance in these difficult cases.

In presence of hæmothorax with fever, we need not intervene so long as the dulness and dyspnœa and displacement of the heart do not increase; we need merely keep a close watch over the patient. It is otherwise when these signs show a tendency to increase ; in fact, the indications are the same as in ordinary pleurisy, and we must perform thoracentesis. If the liquid be sterile this will suffice, but if septic or fœtid or distinctly purulent, then we must perform pleurotomy. If, on the contrary, the aspirator withdraws pure blood, I think thoracotomy should be done.

(4) We meet with cases of hæmothorax in which, though the effusion does not increase, it displays no tendency to become absorbed. When this is the case there is probably some inflammatory complication even in the absence of any rise of temperature. The indication is for pleurotomy preceded by costal resection after, of course, having made an exploratory puncture to find out the nature of the liquid in the chest.

So far, I have been discussing the cases of patients who are taken where a perfectly aseptic operation is practicable, but it often happens that these conditions are not obtainable. In this event it is best to abstain from any sort of intervention, merely placing the patient absolutely at rest after cleansing the wound and applying an occlusive dressing. We may administer an injection of adrenaline or horse serum if this can be procured. If, in spite of these measures, the hæmorrhage continues to increase, the only plan is to slightly enlarge the thoracic wound, introducing a Lister's forceps and separating the branches so as to let the air slowly enter the chest. In a case treated in this way by Lelageniere, the pulse returned and the hæmoptysis diminished. The wound was then sealed and the patient made a good recovery.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Sheffield Neave, B.A.Oxon., M.R.C.P.Lond.; Physician to the Queen's Hospital for Children, London. Subject : "Pyrexia."*

ORIGINAL PAPERS.

MIXED INFECTIONS. (*a*)

By I. WALKER HALL, M.D.,
Professor of Pathology, University of Bristol; Pathologist, Bristol Royal Infirmary.

Mixed bacterial infections are responsible for many puzzling groups of symptoms. The difficulties of diagnosis are increased because at one time there is a summation of effects, and at another the secondary results are more or less overshadowed by the predominant organisms. To take the case of tuberculous infections : the exudative pneumonia which occurs is generally the result of a secondary invading pneumococcus ; the exudates in tuberculous pleurisy are almost always pneumococcal at first, the pneumococcus dying out later and leaving the fluid sterile ; the hectic fever is probably due to the action of other organisms.

A mixed infection, however, need not necessarily be purely bacterial. Protozoal lesions may be altered by the entrance of pyogenic cocci, and some of the filtrable viruses act in concert with schizomycetes.

The primary organisms may damage the skin or mucous membranes, and so provide an easy entrance for the secondary organisms, as in tuberculosis, typhoid, dysentery or variola ; or the primary organisms may damage the general body resistance, and so favour the action and spread of secondary organisms. The frequency of pneumococcal infection in typhoid fever and erysipelas illustrates the latter type.

In the spread of the mixed lesions certain fairly definite changes may be expected. The associated organisms may remain localised, as in the case of tuberculous skin lesions infected later with staphylococci. Or both types of organisms may be generalised, as in combined tuberculous and streptococcal infections, typhoid and para-typhoid, etc. Or the primary factor remains localised, and the secondary one becomes generalised. This occurs in the secondary infections of measles, scarlet fever and smallpox, in influenzal conditions with a secondary streptococcal manifestation in the exudates, in the streptococcal lesions occurring during diphtheria, etc. Or the primary agent may become generalised, and the secondary organism remain localised, the most familiar instance of a very long list being the localisation of the staphylococci and streptococci of a tuberculous cavity, while the tubercle bacillus extends into distant parts.

These features are easily demonstrable. Less apparent but equally important is the condition of sub-infection or sub-intoxication in relation to additional infection. The raids of bacteria present in the alimentary and genito-urinary cavities into the systemic spaces are not always unsuccessful. Now and again a few organisms remain undestroyed, manage to live at starvation rates upon the organic secretions, and constitute what has been termed "latent" bacterial action. They may, however, do more than this. Existing comfortably, without much propagation, they may bring about a condition of doubtful sub-infection, that is to say, a stage of invasion of the tissues which is neither a success nor a failure—a stalemate. On the other hand, the metabolic products

---

(*a*) Paper read before the West London Medico-Chirurgical Society.

of the bacteria, or the action of the bacteria upon protein materials, may depress gradually the nuclear activities of the whole body, and thus convert the doubtful local sub-infection into a definite one. In such a case the individual does not present any noteworthy symptoms. He may, however, fall an easy prey to some epidemic disease and receive the treatment for that disease, whereas he is really suffering from a mixed infection, and will not be cured entirely before both exciting agents have been dealt with.

A symbiosis of this kind calls for more than one method of attack. It is not simply a haphazard association of two or more different organisms situated in separate foci and acting individually. There is generally an interaction, and in some cases a combined action. The presence of staphylococci in a tuberculous focus leads to an increased virulence on the part of the tubercle bacillus ; the bacillus typhosus acts more intensely when it is associated with the streptococcus. When the bacillus coli and the streptococcus are present under conditions of a raised acidity the streptococcal influence is depressed, while a lowered acidity, or an alkalinity, allows the streptococcus to gain the upper hand.

It is obvious, therefore, that during the course of mixed infections the bacteria themselves undergo changes which may modify appreciably the ordinary progress towards recovery. Recent investigations have shown that parasites possess very real and efficient powers of adaptability and mutation. There appears to be a continuous adaptation on the part of the micro-organism to the resisting processes of the cell nuclei, as well as to any chemio-therapeutic substances artificially introduced into the tissues. The adaptability and mutative changes naturally become more complex when several interacting agents are concerned.

The diagnosis of mixed infections from the bacteriological standpoint is fraught with many pitfalls. In an apparently pure infection a second micro-organism, or virus, may be present. When two types of bacteria are isolated from pus or other material, it is important to determine their pathogenicity. When more than two organisms are present their relative dependence and altered virulence have to be considered. To this end it is not sufficient simply to demonstrate morphological or cultural characteristics. Their behaviour when placed in the tissue fluids of the host and their defence against the forces of phagocytosis call for investigation. In other words, the resistance of the host requires to be examined. Two cubic centimetres of the serum of the patient should be subjected to ordinary and absorption tests for the content of agglutinins, precipitins and, in some cases, opsonins ; while, in addition, the identification of specific protective ferments by clinical methods and estimations of the combining powers of the anti-bodies by serological procedures may be indicated. Routine blood counts are also helpful.

The treatment of these infections is not always straightforward. There are but few bacteria which lay down their arms at the first sound of battle, or even fall victims to one kind of ammunition. Diphtheria and tetanus bacilli are made less harmful by the use of antitoxins, but they are not thereby rendered incapable of producing more toxin. In the former instance the simultaneous use of a bacterial emulsion or a solution of lipoid material may bring about the more rapid disappearance of the organism ; in the latter, the future may reveal the necessity of supplementing the serum injections by a bacterial emulsion composed of the organisms which furnish the symbiotic conditions necessary for the propagation of the tetanus bacillus, with the view to the removal of the assisting organism, and a consequent inhibition of the growth of the tetanus rods.

In some cases it is best, perhaps, to aim at the removal of one organism alone, and to leave the other one to natural processes. The injection of artificial serum containing lysins, opsonins, antitoxins and antiferments constitutes one of the best of measures. Unfortunately, this can be used only for a short period, and for the tiding of the patient over difficult crises. The dangers associated with family and individual idiosyncrasies materially restrict its use. Recourse must be had to the injection of bacterial emulsions with the view to stimulate the tissues to a better defence. Of late, however, the *sensitised* emulsion, or vaccine, has taken its place as a better means of treatment. A sensitised emulsion combines the properties of the serum and the emulsion. The bacteria are treated with a corresponding artificial serum, and during their contact with the contained antibodies they become altered in such a way that upon subsequent injection they stimulate the body cells to form more suitable protective substances, as well as serve as the means of conveying the antibodies of the serum to the tissues. The sensitised emulsion has further advantages in that it is less irritating locally than the ordinary emulsion, and that much larger doses of the micro-organisms may be given. It has also valuable prophylactic properties, and merits a routine use prior to operations and to childbirth. The sensitisation is generally carried out with horse or other animal sera, but now and then it has proved advantageous to use the patient's own serum or fluid exudates. In gonococcal, influenzal and similar infections such a method is almost imperative.

Another combination which the future may bring into vogue is the association of serum, or bacterial emulsion, with drug therapy. The action of pneumococcal serum is enhanced by the simultaneous use of quinine derivatives, such as ethylhydrocuprein. Serums associated with cerebro-spinal conditions have proved more potent in connection with oleic and boric compounds. Anthrax anti-serum has been augmented by the administration of salvarsan. Tuberculin injections have proved more beneficial when given in connection with solutions of lecithin. Antityphoid measures have recently been supplemented by a combination of metallic solutions. Further experimentation is necessary before these methods obtain general application ; but their mention is perhaps of value in order to emphasise the necessity of treating bacterial lesions by combined and not by unified treatment. The bacterium learns to defy the stock cartridge in a few generations, that is in a few hours, and can laugh accordingly at the ineffectual attacks of the subsequent "pin-pricks."

Whether the treatment is directed against an individual bacterium or against two or more at the same time, the most important factor in the result is the estimation of the extent of adaptation manifested by the infecting agent. Is the originally predominant organism still the chief offender, or has another one taken its place ? Has the one or the other altered its characteristics in such a way as to render the emulsion, serum, sensitised vaccine or drug of little avail? These are questions which call for an answer in every case. At all events, when the treatments appear to fail, the method employed should not be regarded as ineffectual until an attempt has been made to provide the necessary reply.

In mixed infections also the factor of previous immunisation plays a part. Subsequent inoculations may show that the rate and mode of reaction have been altered. The production of protective bodies may be more rapid and abundant, or they may not occur at all. On the other hand, there may be an increased susceptibility. The observation that when an immunity to bacillus coli is induced the injection of dead staphylococci will raise the agglutinating power of the serum for bacillus coli illustrates the problem looked at from the standpoint of mixed action. Reactions like these appear to border upon anaphylactic phenomena. Little as we yet know of their biological significance, their recognition impresses upon us the futility of injecting unknown stock emulsions without due consideration of the factors already determined. Discredit, personal and general, will not be avoided unless the treatment of bacterial infections by anti-bacterial measures is undertaken with a fuller knowledge of the after-effects than is now deemed necessary.

GRAVE ACCIDENTS CAUSED BY THE ELECTRIC CURRENT.

By PAUL ROSTAINE, M.D.,
Ex-Director of Clinical Medicine at the Paris Faculty.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE rapid development of the electrical industry during the last few years has been followed by a considerable increase in the number of grave accidents. Statistics show that their number is increasing by leaps and bounds, in consequence of which the French Government has appointed a commission having for object to revise the standing rules as to rendering assistance to the victims and the precautions to be taken by the rescuers in order to avoid further disaster.

After two years' investigations, this commission has now completed its investigations and has formulated certain recommendations which are of general interest, especially to practitioners who are liable to be called upon to deal with these cases.

Some of you may remember the narrative of such an accident in which the first victim is, unfortunately, not the only one because brave but inexperienced men have rushed to the rescue, risked their lives and lost them in consequence of not knowing how to protect themselves.

Powerful currents are, even now, hardly general enough for their dangers to be familiar to the public. A line through which a comparatively powerful current is passing does not differ in appearance from a simple telephone wire, so that there is nothing to warn us of the danger.

There is one fundamental fact which is not sufficiently known, *viz.*, the importance of perfect insulation from the ground in respect of alternating currents. It is generally assumed that there is no danger unless one touches both wires, but this idea is completely erroneous, even when the lines are perfectly insulated from each other, unless the body itself is completely insulated from the soil. With a continuous current on a properly insulated line, this danger is not present if only one line be touched, because the body would not be subjected to any difference of potential. There is always considerable risk, however, in touching a line carrying an alternating current of high tension, the danger being in proportion to the capacity of the line.

Everything connected with electricity is more or less mysterious for those not familiar with its properties. This mystery is present in the electric accident, at any rate at first sight. A man, says Weiss, accidentally receives a shock from a current possibly not of any very great strength, yet he is left a corpse. The body bears no external trace of injury, and *post-mortem* examination does not reveal anything, the most expert pathologists discovering nothing to explain death.

Then we meet with another instance in which the accident is of a terrible kind. Various parts of the body that have been in contact with the wires are extensively burned, the burns may be deep enough to expose the bones, indeed, limbs may have been amputated, yet the subject survives! I remember such a case, which is certainly not unique, in which the unhappy victim lost both forearms and both legs without his general health being affected.

This disparity of effects is disconcerting, and the Commission set to work to explain them. Haking sought to throw light on the matter by analysis of carefully observed instances of lightening stroke, of accident and electrocution they ultimately devoted their attention to laboratory experiments which alone rendered it possible to carry out a complete and methodical study of the effects of the current.

Prevost and Batelli were the first to demonstrate by their experiments that death in accidents due to electric currents was due to arrest of the heart in fibrillary tremor or to inhibition of the nerve centres with arrest of breathing.

Without going into the details of the experiments carried out on dogs, we may give the principal conclusions. These observers established the comparative importance of tension and intensity and the connection between the points of contact and the physiological effects observed, and they showed the difference of action of the alternating and continuous currents respectively.

The tension of a current is represented practically by its voltage, its intensity by the number of amperes or milliamperes. It is not the tension but solely the *intensity* of the current that determines the dangerous effects.

In one experiment the tension was 42 volts, and the intensity of 42 milliamperes. The current was made to pass for 50 seconds. Directly the current was turned on all the muscles became strongly contracted and powerful expiration was followed by almost imperceptible respiratory movements which in the course of twenty seconds slightly increased. On cutting off the current, the respiratory movements became extremely active, but gradually subsided and soon returned to normal. With regard to the heart, on turning on the current there was a sharp rise of pressure, varying during the passage of the current; but the heart continued to beat regularly though somewhat more rapidly. On cutting off the current there was a sharp fall of pressure, the heart continued to beat, and in the course of a few minutes everything had returned to normal.

In another experiment, with a tension of 4,500 volts and an intensity of 45 milliamperes, the results were the same, but as soon as the intensity was doubled the heart stopped in fibrillary tremor.

In these experiments the electrodes were applied in perfect contact, one on the right fore paw, the other on the left hind paw, so that the heart was in the track of the current. Under these conditions, as soon as the actual intensity of the current rose to from 70 to 80 milliamperes, the heart at once stopped in fibrillary tremor, *i.e.*, in four or five seconds. As the intensity was increased, death took place more and more rapidly, but the current never took less than one or two seconds to act. Above a certain strength, that is to say, over five or six amperes, the heart does not stop, but we get terrible burns at the points of contact.

When the current is below from 70 to 80 milliamperes death may take place all the same but by a different mechanism. Under the influence of the current all the muscles of the body are tetanised, intra-organic combustions are very intense, and hæmatosis being unable to compensate therefor, death occurs from asphyxia in a few minutes. This piece of information is of the greatest importance in view of the steps to be taken to save the victim of such an accident, *i.e.*, one in which the current is below 80 milliamperes.

If the heart does not happen to be in the direct line of the current the effects are very different. In one experiment with the electrodes at the top of the head and under the chin, a current of 1,080 volts tension and 400 milliamperes was passed for 35 and 58 seconds without causing death. The nerve centres are therefore more resistant than the heart. A current which is fatal to the latter is not lethal to the nervous system. The effects are: Arrest of respiration without stoppage of the heart and resumption of respiration as soon as the current ceases to pass.

The remarks made above also apply to the alternating current. From the point of view of electrocution, properly so-called, we get absolutely the same effects whether the current be alternating or continuous, but it takes about four times as strong a current to kill the animal.

The continuous current, however, causes accidents peculiar to itself, even when of comparatively moderate strength and with apparently trifling lesions. The victim of an accident with an alternating current which has severely burned him has nothing further to fear once he has recovered. It is otherwise with the continuous current. A man whose hands have been burned, the current having passed from one hand to the other, recovers soon enough from his wounds, but he complains of marked loss of power in the arms, and this tends to get worse, so does the muscular atrophy. In spite of treatment of any kind he may ultimately lose the use of his arms, and this fact has an important bearing on prognosis in certain working men's accidents.

The grave accidents due to electric currents are not limited to industrial centres; we occasionally meet with them in private practice under special conditions. The ordinary town current is 110 volts for lighting purposes, and this is practically devoid of danger. One can safely handle a switch because the contact is imperfect, but it should be borne in mind that a current of 110 volts becomes dangerous if the contact be too perfect, *i.e.*, with wet hands or over large areas.

Professor Weiss relates three characteristic cases of the kind. A cook took hold of an electric lamp with a wet hand, while, with the other, she tried to draw water from the tap. She fell electrocuted, owing, no doubt, to the wires being leaky. In another instance, a person, in a bath tried to move a 110-volt lamp and was killed. Here again there must have been defective insulation. His third case was that of a workman who was cleaning the inside of a boiler against the side of which he was leaning with his back wet with perspiration. He had occasion to grasp the electric lamp which lighted the boiler, and was electrocuted. M. Zacon, labour inspector, had occasion to enquire into the case of a workman who was working on the Metropolitan Railway in Paris and was replacing a broken lamp by another. The latter broke in his hands and he fell dead, and at the autopsy no lesion or sign of injury could be detected.

Such accidents are rare, it is true, but workmen are always exposed to the risk when working in damp places. For this reason a low tension, in certain damp industries or places, may prove as fatal as a much higher tension in dry surroundings.

The conclusions formulated by the Commission of Enquiry may be summarised as follows:—

The victim should be withdrawn from contact at the earliest possible moment, and this is the more difficult the more moist the surroundings.

With alternating currents of less than 150 volts and continuous currents of less than 600 volts, the rescuers do not run much danger, provided they only make use of one hand, wrapped at any rate in dry linen, and are standing on dry ground, or, still better, on a platform built up of a plank placed on bottles, glasses or earthenware bowls.

With currents superior in strength to the above but less than 6,000 volts, it is still possible to effect a rescue by rigging up an isolated stage to cut off the earth contact and protecting oneself against contact with the victim by layers of cloth.

With currents above 6,000 volts, all attempts at life saving are inseparable from the gravest risks and the least negligence may precipitate a catastrophe.

In domestic installations at a low tension the principal precaution is to avoid touching the conductors. The hands should be protected with dry cloth, and only one hand employed; lastly, always the rescuer should make a point of standing on a dry plank.

The main principles of treatment are to try and revive cardiac contraction by injections of ether and caffeine, artificial respiration and rhythmic traction of the tongue.

CONDUCT IN THE FEEBLE-MINDED CRIMINAL. (a)

By MR. O. F. N. TREADWELL,
Medical Officer, H.M. Prison, Parkhurst.

In this short paper upon conduct in the feeble-minded criminal I have no intention of touching upon all the phases of conduct to be observed in that class of person. I propose to confine my remarks mainly to some forms of disorder of conduct observed in them while under custody in institutions and when subjected to institutional discipline: conduct which is so frequently alluded to as "criminal" or "anti-social" in type, and which makes the management of that class so troublesome.

(a) Read in the Section of Forensic Medicine, International Medical Congress, London, 1913.

It will, I think, be advisable that I should, in the first instance, define what I mean by a criminal, enumerate the classes of cases which in the prisons come under the title of feeble-minded, and briefly describe how they come to be differentiated from the rest of the prison inmates, before considering types of conduct in particular, responsibility, punishment and treatment.

A criminal is taken to mean a person who has committed some offence which has resulted in his coming to prison under a term of imprisonment or penal servitude.

The term "feeble-minded" or "weak-minded" is used in prison parlance to denote all kinds of mental disorder which appear to indicate lessened responsibility. It is sufficiently comprehensive to include several classes, in all of which there is to be observed mental defect, ranging from slight degree of divergence from a standard, called by the observer the normal, to conditions of mental alienation just short of certifiable insanity.

The classes include all those who exhibit congenital defect, or defect apparently arising in early life, defect indicating imperfectly developed stage of insanity, mental impairment after attack of insanity, and defect due to senility or alcohol.

Excluding such cases of the imbecile type as are readily apparent on a cursory examination, it will, I think, be found that the conduct of the prisoner in prison is often the first factor to draw attention to his case. This is shown by his apparent inability to conform to prison discipline, the frequency of his reports for misconduct, or his reaction when under punishment, which, instead of deterring him, provokes him to further acts of insubordination of a more aggravated character.

An examination into his criminal career possibly reveals the fact that he commenced it at an early age, that he has a long list of previous convictions standing against him, or that his crime is one which is found to be commonly associated with feebleness of mind—*e.g.*, stack-firing, sexual offences against children, and other unnatural acts.

Now the evidence of even a very bad record in the direction I have indicated would of itself hardly justify us in placing the prisoner in the feeble-minded class, and it must be within the experience of all those who have to deal with criminals to come across some, from time to time, whose record of crime and of misconduct in prison could hardly be exceeded, but in whom no other evidence of mental defect could be observed, who were nevertheless alert and intelligent and without prominent stigmata of physical degeneration, and who could not be looked upon as other than merely vicious. A careful examination, however, into the intellectual capacity of these badly-conducted prisoners usually reveals some co-existent defects upon the intellectual side, indicative of a low level of intelligence and often accompanied by some of the characteristics of physical degeneration, and it is from the sum of the various factors observed that a classification of feebleness if mind is arrived at.

Now it is obvious that some of these various characters may exist in the ordinary criminal; that it is not the presence or absence of one or two, but the significance to be attached to the presence of several in the same individual which is of importance; consequently, that there must of necessity be considerable divergence of opinion upon the propriety of the classification of some of the difficult border-line cases, and doubts must arise as to whether they are examples of feebleness of mind or simply of vice. These border-line cases often give much trouble in the management of prisons and institutions in which they are incarcerated, in consequence of the disorder of conduct to which they are prone. Their physical conformation is quite up to the average, their conduct is bad, but the evidence of defect of intelligence is meagre, and it is impossible to be sure that we are not dealing simply with depravity. Each case can only be decided upon its merits in accordance with the experience and judgment of the observer.

Coming now to the disorder of conduct exhibited by these feeble-minded criminals in prison, there are some forms which, though not solely confined to the particular class under consideration, are much less frequently met with in the habitual criminal of average intelligence and rarely in the criminal of higher intellectual level. I refer to such grave disorder as filthy conduct, defiling of self and cell, destruction of utensils and clothing, the use of foul and obscene language, etc. In parenthesis, I might add here that these grosser departures have, within my experience of some thirty years, become much less common than they used to be, and this has occurred *pari passu* with the lessened rigour of prison discipline.

Another phase of disorder of conduct often seen in the criminal of feeble mind, but rarely in the habitual of average mind, is obstinacy pushed to an extreme degree; such, for example, as persistent refusal to perform any work over a considerable period of time.

Repeated misconduct is another phase of disorder to be observed amongst these feeble-minded criminals. Reported and punished for some minor offence, the prisoner at once commences an aggravated form of misconduct; reacting in one of two ways, either by protesting vehemently by violence, destruction of clothing, noisy, threatening, foul and abusive language, or by becoming sullen, morose, obstinately silent and negative in demeanour, and refusing to speak or stand up or to do anything he is told. At a varying period after the outbreak he will become amenable, will converse on the subject of his misconduct and listen to argument, perhaps attempt to justify it, or possibly plead that he could not help it, and will probably promise amendment for the future; but his promises are of little value, and it may be confidently predicted that sooner or later a similar train of events will occur.

These reactions are met with in the ordinary habitual criminal, but much less frequently and persistently. In the criminal of the higher intellectual type they occur very seldom, and then the question of early insanity at once presents itself for careful consideration.

What is the degree of responsibility of the feeble-minded criminal for these acts? There can be no doubt, I think, that he knows them to be wrong; in fact, they are often apparently done with the intention of doing wrong; to mark his contempt for those in authority, and to give as much trouble as possible. But when one finds the same prisoner continually behaving in a similar manner, reacting in the same way, and so regardless of the fact that his own self-inflicted discomfort is out of all proportion greater than the annoyance he is causing to others, the question arises whether he is fully responsible; whether his power of controlling his actions is fully up to what should be a normal standard; whether he has an average power of reasoning and judgment at the time, or whether the more elaborate mental processes engaged in reason and judgment are so slow or perverted that he cannot be held to be completely responsible. It is, of course, difficult to justify a plea of partial responsibility; but this concept has become usual in practice, and without doubt has tended to modify the punishment awarded.

That some notice must be taken of these disorders of conduct and some form of punishment, such as loss of diet, confinement to cell or room, or deprivation of privilege, must be administered, will, I feel sure, be admitted by all who have had to deal with this class of criminal. To take no notice of his delinquencies would certainly be put down to weakness by the prisoner himself and lead to continued acts of insubordination; but I think we are justified in our methods of modified prison discipline and modified punishments suitable to each individual case as it arises, judged upon its merits at the time and guided by the results achieved.

There is little doubt, I think, that the conduct of these feeble-minded criminals undergoes much modification in accordance with their environment. Under the ordinary prison discipline it may be bad, and, as I have previously pointed out, it is often the inability to conform to ordinary prison discipline thus shown which brings their mental state under particular observation. When they are removed to the feeble-minded parties under modified regulations and specially selected attendants their conduct greatly improves.

It will be of interest to consider the question of insanity in its connection with these feeble-minded criminals. They account, I think, for a considerable number of the so-called criminal type of insane patients. During the seven years that the Criminal Asylum at Parkhurst was in existence, out of 226 patients who passed through that establishment, 136 had been previously classed as feeble-minded in the prison—*i.e.*, 60 per cent. The point is of interest in its bearing on the conduct of this type in the general asylum. It is considered by those responsible for their management very undesirable to have this type in ordinary asylums, and I can well understand the difficulty they create and the undesirable influence they exert upon other well-behaved inmates.

Their conduct is described as being often due to their criminality and not to their insanity, but I take great exception to the word criminality in this sense. The ordinary well-behaved criminal who becomes insane differs not at all from other insane patients. The point is worth consideration: whether these insane patients from the prisons who exhibit this disorder of conduct are not feeble-minded in addition to being insane; whether the conduct so much complained of is not the manifestation of this underlying feebleness of mind, and the fact of their having been in prison a mere interlude in their history. It has been said that feeble-minded paupers in the asylums do not exhibit these same disorders of conduct. But is this relevant to the subject at all? If their conduct is of disorderly character before they become insane they are sent to prison and thus stamped as criminals, and presenting as they do feeble-minded traits in the particular direction of acts against social laws, prison is the only place to which they can be sent before they become insane.

There is no necessity to labour this point. It has been suggested that this type of insane person should be treated in a criminal asylum and not in a general asylum. I am quite in agreement that careful segregation in separate establishments or blocks is what should be aimed at, upon a classification based upon conduct; and whether in asylums or in prison or in institutions for the feeble-minded, the more complete the segregation of one class from another, the better the conduct of all is likely to be.

The following point has perhaps not been fully appreciated. When a feeble-minded criminal of the badly-conducted class is placed amongst those who are well-conducted, he is, of necessity, kept under special surveillance, the attendants are constantly watching him, certain forms of labour, if he is of the violent type, are not open to him, privileged positions of trust are necessarily denied him, and he is in a continual state of discontent, brooding over a sense of injustice at the favouritism, as he calls it, which is shown to others. Does not this same treatment follow him everywhere, even to the asylum if he should become insane? His segregation in separate establishments, or blocks, where more equal privileges can be afforded, may lead to less discontent and less disorder of conduct.

A NOTE ON A NEW URINARY ANTISEPTIC.

By T. THOMSON RANKIN, M.D.Glas.,
Medical Officer to the Workhouse, Parish of St. Giles's Camberwell.

As the condition of the urine is of great importance in general practice, any new light thrown on the subject—especially from the therapeutic standpoint—should be of general interest. For all practical purposes the urine, in a healthy individual, is the pure and unaltered excretion of the kidneys. Under ordinary circumstances, it is perfectly clear, is acid in reaction, and has a characteristic aromatic odour. It is to alterations in these conditions that one would like to call attention.

Every practitioner comes across cases in which the urine becomes turbid, alkaline, and evil smelling, and in an institution like this such cases are numerous. The symptoms and effects of this condition are distressing to the patient and to those who come in contact with him. The condition is aggravated when the patient is incontinent and everyone is familiar with the results. If the patient is of a sensitive disposition his state of mind can only be imagined and the duty of the attendants is one that is not to be envied. The common causes of such a condition are cystitis, enlarged prostate, malignant disease of the bladder, paralysis, and senility. As bacterial action is directly responsible for the evils referred to, it is natural that one's attention should turn to urinary antiseptics, of which there is an increasing number. There is no doubt that the treatment of such cases presents great difficulties to the busy practitioner, and anything that will be of any help deserves the attention of all.

The urinary antiseptics that are commonly used are, benzoic acid, boric acid, salicylic acid, and hexamethylene-tetramine. The effect of these drugs is well known, and some of them are undoubtedly of value. The great drawback to the efficiency of those that are of any use is the fact that they are liable to produce unpleasant effects, such as gastric and renal irritation, constipation, and impairment of appetite. A drug that would be of value and would not cause any unpleasant effects would be a boon.

During the past seven or eight months the author has been dealing with a number of these distressing cases, and has been impressed with the necessity of doing something to relieve the troublesome symptoms and unpleasant coincident distress. It must be admitted that the treatment of symptoms, such as this appears to be, is not scientific, but one must consider the feelings of the sensitive patient as well as the surroundings of those constantly attending the case.

Before going any further, it may be stated that the treatment of the symptoms has been carried out in a way that will appeal to the busy general practitioner. In fact, the conditions here are not unlike those of general practice. There has been no elaborate bacteriological investigation or no special accessory treatment. The aim has been to relieve the burdens of the patients and attendants. One, of course, recognises the fact that such investigation is necessary in hospital work. The results of the treatment have been most satisfactory, and therefore it is one's duty to record the nature of the treatment. The drug that has been used is cystopurin, a combination of hexamethylene-tetramine and sodium acetate. This drug was used in preference to other urinary antiseptics because others had been used by the writer previously without giving entire satisfaction. They either failed to give adequate relief or caused unpleasant symptoms and had to be given up. A few words on this drug are therefore necessary. It is put up in tablet form, each tablet containing one gramme. There are two parts of sodium acetate to one of hexamethylene-tetramine. It is easy to take and causes no unpleasant symptoms. In proof of the latter statement, the drug has been given in varying quantities and over varying periods. The largest dose has been four tablets four times a day. Some cases had one tablet three times a day, others two three times a day, others three twice a day, and so on. The initial dose in most cases was one tablet three times a day. This dose was gradually increased as required. In no case was any unpleasant effect noted. The period over which the drug was given has varied from one week to four months.

The effects of the drug were (1) it relieved any irritation or pain present. (2) It cleared the urine and made it more transparent. (3) It caused diuresis. (4) It diminished the alkalinity and rendered the urine less unpleasant. It was also noted that the effect was more or less lasting and that when the drug was discontinued the good effects did not disappear at once. If, after a time, the condition returned, another course was beneficial. During the time that the drug was given, the previous habits and diet of the patient were not interfered with, and no extra treatmen was given. The combinaion of urotropin and sodium acetate has been questioned on theoretical grounds, but the practical application has not supported these objections.

It is not necessary to quote all the cases treated, and the following will be sufficient for the purpose :—

Case 1.—W. M. Enlarged prostrate. Incontinence; æt. 64.

This patient had alkaline urine with pyuria. The unpleasant symptoms were present in full force. He was given two tablets of cystopurin twice a day. For four days no effect was observed, but on the fifth day the pus had disappeared although the urine remained alkaline. This state of affairs lasted three days. After that, the urine became neutral, and in a few more days it became acid. This was a result most pleasing to the patient and those attending him. The drug was continued a few days longer and then discontinued. The good effects lasted two or three weeks and then returned the old symptoms. A further course soon established the desired effect again.

Case 2.—E. C. Arterio-sclerosis. Senility; æt. 70. This case was similar to the last and the treatment was the same. In this case, however, the good effects were observed on the third day.

Case 3.—W. L. Enlarged prostate. Thickened arteries. Stricture; æt. 59.

This patient had urinary trouble for many years and gave a history of stricture. The urine was very alkaline and contained a large amount of pus. He had pain on passing urine. At first he had two tablets of cystopurin twice a day. This was continued for ten days. The first five days showed practically no improvement. After that the pain diminished, the amount of urine passed increased, and the reaction varied from faintly alkaline to acid. He was then put on three tablets three times a day for a month. This had the effect of increasing the acidity of the urine but had no effect on the pus. The drug was then stopped for a week and then given three times a day (two tablets) for a month. The result was the same—the reaction remained acid and the pus continued. Three tablets were then given three times a day for three weeks without any change. Then the dose was increased to four tablets three times a day for a week. Still no change was observed. Finally, four tablets were given four times a day. The result was the same: the pus persisted. All this time there was no ill effect and the appetite was not impaired. It was then seen that the patient had a stricture about the middle of the urethra and a chronic urethritis. This was the most unsatisfactory case of all, yet the conditions were much improved and the patient felt better.

Case 4.—W. P. Cystitis. Thickened arteries; æt. 65.

Practically in all respects this case is the same as the last, with the exception that the drug was not given in such large quantities nor for such lengthened periods. The pus continued for weeks although the urine was acid. The discomfort was diminished, the urine increased in amount, and the disagreeable odour disappeared. This patient had nine tablets a day as his largest dose, and after many weeks the pus disappeared from the urine.

These four cases are given as examples. The first two show the drug at its best, while the latter two show the worst cases. Where the results obtained are not satisfactory after a few weeks, it would be advisable to try adjuvant treatment, such as washing out the bladder and the cystoscope and bougies might be called into service to aid the diagnosis.

To sum up, the effects of cystopurin are: That it relieves urinary pain and discomfort, renders the urine less offensive, causes diuresis, clears turbid urine, produces no ill effect, is well tolerated, and seems to have no harmful cumulative action.

DR. EDWIN WM. ALABONE, ex-M.R.C.S., of Lynton House, Highbury Quadrant, N., left estate of which £25,041 is net personalty.

OPERATING THEATRES.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

CASES OF CONGENITAL DISLOCATION OF THE HIP.—MR. EDRED M. CORNER showed the results of cases treated successfully by the so-called bloodless method of Lorenz. The younger the child, he said, at the time of treatment, the better the result. These children were slow to learn to walk, and in consequence their disability and condition were not noticed. Until such notice had been taken, the parents or guardians did not bring the child to the doctor. Thus it was very unusual to have for treatment a child under 1½ years of age. Under two years children of the upper and enlightened classes were sometimes brought to our notice. But in the hospital class of patient, children of all later ages would come up suffering from congenital dislocations of the hip. Perhaps the parents or guardians had not the time or intelligence to notice that something was wrong. Or it may be that they noticed that the patient was different to other children, but they did not think or know what to do to set matters right. This age-factor was very important, as up to the age of five, or even seven, it was possible to reduce by manipulations almost all dislocations of the hip. If the child is above that age manipulations are likely to fail, and we have a choice of either leaving the child alone or operating.

The method of operating Mr. Corner now demonstrated. An incision is made from just below the anterior superior spine of the ilium downwards, across the femur below the trochanter, and upwards on to the buttock, and not so high as the point where the incision begins. The flap thus outlined, consisting of skin, fat and fascia, is turned upward. The anterior edge of the gluteus minimus is defined, as it stretches from the ilium to the top of the great trochanter, an elevator thrust under it and pressed downward on to the neck of the femur. With a thin saw the tip of the trochanter with the muscles attached to it, is separated and drawn upwards. The neck of the femur and the outer surface of the ilium are then exposed. So far the operation is quick, accompanied by little bleeding, and gives the best exposure of the hip of any method. Next the head of the femur is freed and the dislocation reduced.

It will be seen, Mr. Corner said, that the wound is in an awkward situation, and is easily infected in the nursing of the patient. Therefore it is desirable to seal the wound as quickly as possible, and because of the awkward situation of the wound to use in doing it absorbable sutures. Hence it may be noticed that he approximated the margins of the wound with five or six rectangular mattress sutures of catgut, co-opting the cut edges with a continuous suture of ten-day catgut, the stitches being close to the edges and close to one another.

Mr. Corner then gave the history of three cases :—

(1) Double congenital dislocation of hip. Operation. A child, æt. 10, was admitted to the hospital. The left hip-joint was operated upon. The joint was exposed as advocated and the femoral head set free, the acetabulum was enlarged and the dislocation reduced with a fascial flap interposed between the acetabulum and the head of the femur so as to ensure good movement. The division of soft parts led to oozing and the wound was drained temporarily for 24 hours. The limb was fixed in the abducted position with plaster of Paris. A skiagraph taken a few days after operation showed that the head of the femur was not in the acetabulum, but in front and below it. Of course, this may have resulted from a chance movement, but Mr. Corner would rather suggest that the anterior and inferior margins of the acetabulum were insufficiently developed to retain the head of the femur, owing to the congenital dislocation, and to prevent the head of the femur slipping out. This possibility should have been sought at the operation, and if present the hip should not have been put up abducted. In subsequent cases he had sought in the developments of the margins of the acetabulum indica-

tions as to the position in which the leg should be put up afterwards. This has led to a modification of the usually accepted position of flexion, abduction and eversion, and he commonly puts these cases in Stiles' hip splint in only slight abduction (useful for nursing purposes) no flexion and no eversion.

(2) Congenital dislocation of the hip, with failure of the method of manipulation, fracture of neck of femur and operation. A child, æt. 5, was sent to the hospital with a congenital dislocation of the right hip-joint. On two occasions Mr. Corner attempted to reduce the dislocation after the method ascribed to Professor Lorenz, of Vienna, but failed to do so. Mr. T. Twistington Higgins also tried. After the final attempt a skiagraph showed a failure plus a fracture of the neck of the femur. All attempts at reducing the dislocation were now suspended, pending union of the fractured neck of the femur. After this had taken place, the joint was exposed after the method advocated. Mr. Corner said it was now easy to see why we could not reduce the dislocation and why we broke the neck of the femur. The capsule of the "false" hip-joint was very strong and the lip of the acetabulum was very large. In consequence the head of the femur could not be made to ride over this lip, the neck of the femur being finally broken in the attempt. With the exposure of the joint given by the method here advocated it was no difficult matter to place the head of the femur in the acetabulum. All went very well, but unfortunately the child developed diphtheria badly, so that the progress of the hip condition has been quite overshadowed by the more serious results of diphtheria.

He remarked that a point in the treatment of these cases is that sufficient time should be allowed to elapse between the fracture and the operation for the union of the fragments to be firm—let us say not less than three months, and six months if possible. In the case just narrated the union was strong enough, but it might have been stronger.

(3) Tuberculous disease in hip-joint, the subject of congenital dislocation. A little girl, æt. 2, was brought to the hospital. According to her parents, the child had been complaining of pain in her hip and had been limping for some months. As the pain had got worse they brought her to the hospital. The ordinary typical signs of a congenital dislocation of the left hip were present. In addition to this there was some rise of temperature, pain in the joint, especially on movement, and starting pain at night. The presence of the dislocation was confirmed by Dr. Ironside Bruce with a skiagraph. An extension on the leg did not ease the pain. An operation was undertaken and performed as had already been recommended. The head of the bone lay carious in an abscess, so that the arthrectomy became almost an excision of the hip. By means of the incision recommended the operation was well and easily carried out in all its phases, so that in six weeks' time the child was discharged from hospital healed and in plaster of Paris. The hygiene of her home was improved and the progress of the child has been forward from that moment. The good result in her case he attributed very largely to the fact that the method of exposure of the joint allowed the surgeon's work to be very well done. There was no evidence that the disease was syphilitic. A feature illustrated by the case was that both the dislocation and the disease were treated at the same operation. A great argument for not leaving these congenital hips alone is that such dislocated hips are prone to suffer from the incidence of disease.

HAMPSTEAD GENERAL HOSPITAL.

Additional remarks by Mr. Jackson Clarke on the cases of appendicitis reported last week.

Two of the three were cases in which a partial colectomy, removal of the ascending and half the transverse colon, and end-in-side implantation of the proximal end of the divided ileum into the iliac colon was done. The third is a case in which the operation is contemplated. In the first case there was no shock and there was complete relief of the patient from pain. In the second the operation was only done after every measure to render it unnecessary had been taken. The patient was a delicate young woman who has complained of pain for years. A right nephropexy was done together with the removal of an adenoma of the thyroid gland three weeks before the partial colectomy. The latter operation was complicated by the presence of tuberculous glands, which were removed with a part of the mesentery. This operation was followed by a serious degree of shock, but the patient made a good recovery.

Mr. Clarke further remarked that he would like to correct a point in last week's report as follows:—"I said that adhesions after appendicectomy, when present at the time of operation, tended to diminish and, judging by the symptoms, to disappear in time. There are, however, a few exceptional cases in which the converse holds good: the adhesions do not disappear, but rather increase and give rise to an increasing amount of pain. The three cases briefly related last week are examples of the latter class."

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Section for the Study of Disease in Children.

Meeting held on Friday, November 28th, 1913.

The President, Dr. Leonard Guthrie, in the Chair.

The following cases and specimens were shown:—

Dr. C. E. Zundel showed a case of "Recrudescent Rickets with Tuberculosis and Infantilism." Former hospital records show that the patient, a boy, now æt. 14, was at the age of 7 years treated as an out-patient and then as an in-patient. At that time he was described as very undersized and with marked rickets. At the age of 11 years he was admitted to the Brompton Hospital with marked ascites, the abdomen being tapped six times in nine months. When he came under observation in June, 1913, his height was 3 ft. 4 ins., and weight 2 st. 11 lbs. Marked deformities of the forearms were present, due to recent fractures. There was some broncho-pneumonia and considerable ascites. Wassermann's reaction was negative.

Dr. F. G. Crookshank and Mr. L. E. C. Norbury showed cases of bilateral congenital dislocation of the hip in twins. The patients were females, aged 8 years 11 months. In each case there was marked displacement of the head of the femur on to the dorsum ilii on either side.

Dr. F. G. Crookshank also showed a case of "Nervous Cretinism." The patient, a female, now æt. 5½, was first seen in 1912, when it was noted that the skin was harsh, the gait tottery, and the knee-jerks increased. Later the gait became more ataxic and the speech became defective. As the result of treatment with thyroid extract the child now walks and talks well, and has lost almost all her symptoms.

Dr. Crookshank also showed a case of "Jaw-Winking." The patient, a girl, æt. 9, has congenital unilateral ptosis. When the muscles of her face are at rest the ptosis is considerable. When she depresses her jaw and "rings" her mouth, not only does the ptosis disappear, but the sclerotic becomes visible on the affected side, above the cornea.

Mr. Philip Turner and Dr. H. Tipping showed a case of a "Mesenteric Cyst" which had simulated an intussusception. The patient, a previously healthy boy, aged 4 months, had a "crying fit," after which blood was passed per anum. After admission to the hospital, a rectal examination showed the presence of recent blood, though no lump could be felt. An anæsthetic was given, and then a movable tumour could be felt close to the umbilicus. When the abdomen was opened the lump was found to be a tense cyst about an inch in diameter, situated in the mesentery in the angle between the ileum and the colon. It bulged into both these portions of the intestine, causing obstruction at the ileo-cæcal valve. The cyst wall was so incorporated with the ileum and the colon that it could not be removed. The cyst was incised, the greater part of the wall clipped away, and the remainder sutured to the parietal peritoneum. The child made an excellent recovery, but a sinus which discharges glairy odourless fluid still persists. Histologically, the lining membrane of the cyst had the same structure as the mucous membrane of small intestine.

Dr. **W. J. Midelton** showed two cases of "Dermatitis Herpetiformis" treated by counter-irritation. The first patient, æt. 7, had scarlet fever when 3 years old, and this was followed by the dermatitis. The disease persisted until February, 1912, when counter-irritation was commenced. The patient was well in three weeks. There have since been occasional slight relapses. In the second case, a boy, æt. 7, the same treatment has been equally satisfactory.

Dr. **G. A. Sutherland** showed a case of "anterior poliomyelitis" with paralysis of the abdominal muscles and collapse of the lung. The patient, a female, aged 15 months, had an indefinite illness thought at one time to be measles, in May, 1913. Three weeks later there was dullness over the right lung, and exploratory puncture was several times performed, with a negative result. When re-admitted in October, 1913, the legs showed signs of former poliomyelitis. The abdominal was prominent, and on crying two marked bulgings were seen, one occupying the upper two-thirds of the right abdominal wall, and the other the lower two-thirds of the left side. Over the right lower lobe posteriorly there were impaired breath sounds. It was suggested that the pulmonary signs were due to massive collapse of the lung, and that this was due to paralysis of the muscles of the abdominal wall.

Dr. **J. W. Carr** showed a case of "enlargement of the Liver with Ascites." The patient, a boy, æt. 2½, was admitted to hospital for ascites in March, 1913, and was tapped on 13 occasions. The liver now extends between two and three inches below the costal margin: it is hard, and the surface feels slightly granular. There had been no hæmatemesis, and only one transient attack of jaundice shortly before his first admission. Dr. Carr considered that the liver was almost certainly cirrhotic, but the cause of the cirrhosis was obscure.

Dr. **F. J. Poynton** showed a case of "Osteogenesis Imperfecta" with great distortion of the bones ot the lower limbs. The patient, æt. 11, has been admitted three times to University College Hospital and many times to great Ormond Street with fractures of the bones of the legs. Her bones have been soft and easily broken from birth, and she has never been able to walk alone.

Dr. **Poynton** also showed a female child, æt. 5, with a slightly enlarged liver and spleen. Examinations showed marked cyanosis of lips, tongue, and throat, and clubbed fingers. No bruits could be heard, but in May, 1913, there was a pulmonary systolic bruit: it was doubtful whether this was congenital or hæmic. Wassermann reaction negative. Also, three children in the same family with alopecia areata.

Mr. **H. A. T. Fairbank** showed a case of ununited fracture of the neck of the femur which he had treated by operation eight years after the injury. When first seen the limb was wasted and held in an everted position. Flexion was limited and abduction practically abolished. Real shortening two inches. A skiagram showed an ununited fracture and coxa vara. The fibrous bond of union was excised, and two screws were driven from the trochanteric surface through into the head. The operation had been successful in abolishing the pain and arresting the progress of the deformity. Mr. Fairbank also showed a case of Osteo-periostitis of the Upper End of the Femur of uncertain origin. There was thickening and tenderness at the upper extremity of the femur, and the child, a girl, æt. 5, limped slightly. The skiagrams suggest an inflammatory lesion, not a new growth. The Wassermann reaction is negative, and mercury and iodides have been given wthout effect.

Dr. **F. Langmead** showed two sisters with deformity of bones and splenomegaly. The first child, aged 6 years 5 months, shows skeletal changes which closely resemble those of rickets. The spleen extends downwards as far as the anterior superior spine of the ilium, and fills the left side of the abdomen. The liver extends down an inch below the costal margin. In the second case (aged 5 years 4 months), the bony changes resemble those in the first, but have developed to a less degree. The spleen is also enlarged, but less so, reaching about an inch below the costal margin. The chief points of interest are: (1) The progressive character both of the skeletal changes and the splenomegaly, and (2) the fact that this is occurring at an age when the usual period for active rickets is over.

Dr. **F. G. Crookshank** also showed skiagrams of a case of Dactylar Deformity from Amniotic Bands.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, November 28th, 1913.

Mr. L. G. Gunn in the Chair.

A CASE OF PAGET'S DISEASE OF THE NIPPLE.

Mr. **R. C. B. Maunsell** and Dr. **Joseph T. Wigham** read a paper on the above subject. Paget's original description was quoted, and an accurate clinical and microscopical description of the case was read. The communication was illustrated with coloured drawings and lantern slides.

Mr. **A. Blayney** said the only point open to criticism was that Mr. Maunsell regarded the case as of the nature of rodent ulcer. From this opinion he dissented. All cases observed terminated in cancer of the breast, and this also was contrary to the theory of rodent ulcer. In most cases of rodent ulcer no enlargement of glands was to be found in the neighbourhood. Although he had an open mind on the subject he was inclined to the view that it was a case of malignant growth of the skin which subsequently spread to the breast.

Mr. **Maunsell**, in reply, said that before, at, and subsequent to operation a search was made for glands, but none were found. He held that it was a sort or kind of rodent ulcer. In his and Paget's description induration was not mentioned. The reason for his conclusion was that the appearance or process of cells was more like that seen in rodent ulcer than anything else.

Dr. **Wigham**, replying, said that the case should be expressed rather as a skin cancer than rodent ulcer. He had never seen a rodent ulcer which grew so freely. The cancer deep in the breast was certainly a difficulty, and whether the disease was one cancer or two, or whether the cancer had grown down into the breast, he could form no conclusion from the observation of this single case.

THE TECHNIQUE OF OPERATION FOR CARCINOMA OF THE BREAST.

Mr. **Pearson** read a paper on the above subject and pointed out the principle on which modern radical operation for carcinoma is based, and enumerated certain secondary principles of importance. These were:—(1) To avoid dissemination and wound-implantation of cancer cells during operative procedures; (2) to minimise hæmorrhage and shock; (3) to minimise the risks of infection; (4) to avoid unnecessary mutilation and loss of function. The scope of the radical operation in favourable cases of carcinoma of the breast, in the light of Handley's investigations, was indicated, and the application of the secondary principles to the procedure discussed. The precise *technique* adopted was then explained with the aid of lantern slides, the special points on which emphasis was laid being—(1) that extensive removal of the fascial tissues with their contained lymphatics was the most important safeguard against recurrence; (2) that the operation, even in the making of the cutaneous incisions, should be regarded as a two-stage procedure—an axillary portion which should be first carried out, and secondly an abdomino-thoracic portion; (3) the use of the deep fascia over the clavicular fibres of the pectoralis major (which fibres might safely be retained in favourable cases) as a guide to the separation of the clavicular from the sternal divisions of the muscle; (4) the use of clamps on the pectoral muscles before division both to act as retractors and to prevent possible dissemination; (5) the systematic exposure and securing of the blood-vessels in such a way that the operation was practically a bloodless one; (6) the necessity for additional drainage, besides the ordinary drain in the axilla, in certain cases; (7) the reconstitution of the axillary vault as the greatest safeguard against subsequent loss of function; (8) the importance of early movements of the arm.

The Chairman emphasised the point that success in curing cancer of the breast depended more on early diagnosis than on the *technique* of the operation, and he considered that if the disease had extended at all far the chances of success were not good.

Mr. Pringle said that his experience did not coincide with that of the writer regarding ordinary cases of cancer. He considered no operation radical where one jumped about from one part to the other. A thing which impressed him with regard to this operation was the importance of keeping the upper ends of the incision well out of the axilla on account of the difficulty of properly sterilising the axillary fossa.

Mr. Keegan recalled a case of his which was met in a very late stage, the axilla being involved, and there was a fungating growth in the skin. The patient returned with a recurrence in the skin, which X-rays failed to remedy, and the affected area had to be removed. It was preferable to have a recurrence in the skin rather than to risk the infection of the mediastinal glands, and he advocated the removal of the clavicular portion of the pectoralis major.

Mr. Stokes joined issue as to the removal of the pectoralis muscle. His experience was that there was no use in doing these enormous operations when the case did not come for operation early. He had only one patient alive four years after operation, and this he considered a case of mistaken diagnosis.

Mr. Maunsell said that his experience was that a large number of cases of cancer of the breast lived long lives after operation irrespective of whether they had glands in the axilla or not. He had one patient alive eight years after operation. He considered the breast a favourable situation provided the operation was done thoroughly. He suggested that Mr. Pearson was not radical enough, and that in every case the pectoral muscles should be removed entirely. He would also be in favour of removing more skin than was suggested in the paper. His method was to carry up the skin incision like a V the whole way in order to get away more skin up towards the deltoid region. The hæmorrhage in these operations was very slight. It was always his practice to encourage the patient to move the arm from the first.

Mr. C. A. Ball said that a point which he considered of importance was the putting in of more than one drainage tube. He had been in the habit of draining the axilla and also putting a tube in the lower end of the wound. He drew attention to the involvement in a large proportion of these cases of the supra-clavicular glands, and would like to know if it was recommended that such should be removed. He recalled a case of his in which a patient of advanced years had a large mass in the breast which was removed four years ago, and she had since shown no evidence of cancer. He therefore recommended the local operation in some cases where an extensive one might, perhaps, lead to bad results.

Mr. Pearson, in reply, said he did not mean that the diagnosis of carcinoma of the breast was easy, but that carcinoma of the breast offered more facility for diagnosis in a curable stage than carcinoma in any other region. The ordinary case should be one which was favourable to removal and should have no involvement of the axillary glands when it came to the surgeon. He would regard glands in the axilla as unfavourable, and in such cases would recommend the removal of these glands. He suggested that if there was any involvement of the supra-clavicular glands, radical operation was contra-indicated. In the favourable cases he thought the clavicular portion of the pectoralis muscle might be left. He suggested that the public should be better educated on this subject with a view to bringing about the earlier treatment of carcinoma of the breast. He did not agree with the method of carrying the skin in a V on the axilla in early cases.

HARVEIAN SOCIETY OF LONDON.

Meeting held December 11th, 1913.

The President, Dr. Leonard Guthrie, in the Chair.

Sir Ronald Ross, K.C.B., F.R.S., read a paper on the

STUDY OF INFECTIONS BY ENUMERATIVE METHODS.

The author drew attention to the advantages of modern investigation by groups of men working together under one head; indeed, he hinted that the time had now arrived when advance of tropical medicine could only be made by organised team effort. Sir Ronald dealt chiefly with the work produced and the investigations carried out by a small team working under his direction in Liverpool, which had worked together for two years on a sum of £900 granted to him from the Home Office. There was a vast amount of work to be done and several very useful advances and observations made; the team unfortunately scattered and the work was abandoned when the money came to an end. The observations dealt chiefly with the intimate characters and phases of sleeping sickness, a new variety of which was actually discovered by these workers, and also the result of drugs on this disease both in man and animals.

Reference was also made to the real nature of blackwater fever and its experimental production on animals. The paper, though highly scientific, proved extremely interesting to all, and was clearly illustrated by lantern slides, and microphotographs, many of which were reproduced in natural colours.

Dr. Sydney Phillips thanked Sir Ronald Ross in the name of the Society for the interesting lecture.

The Annual General Meeting of the Harveian Society will be held on Thursday, January 8th, 1914, at the Stafford Rooms, Titchbourne Street, Edgeware Road, W., when the election of officers for the ensuing year will be proceeded with. Reports will be received from the treasurer and hon. secretaries. Dr. Leonard Guthrie will deliver his presidential address on "The Early Transactions of the Harveian Society." The New President will be invested and the proceedings will be terminated by a smoking concert, the arrangement of which will be placed in the hands of Mr. John Ivimey.

SPECIAL REPORTS.

THE NATIONAL MEDICAL GUILD.

[Specially Reported for this Journal.]

A meeting of medical practitioners in furtherance of the objects of this Guild was held in the Town Hall, Hammersmith, on Friday, December 19th, Dr. C. J. Buttar in the chair.

The Chairman explained that the Guild was registered under the Trades Union Acts, and its Council had recently been impressed by two facts. Firstly, trouble was looming ahead for the profession in a short time; and by 1915, if not before, the whole subject of medical benefits under the Insurance Act would be again under review. And there was great probability that in process of time the dependents of insured persons would be dragged into the Act, meaning that 37 million persons would come under its provisions. The second great fact was, that despite the urgency of the question, there was but little cohesion in the profession, or preparedness for the coming struggle. He reminded the meeting of the collapse of the British

Medical Association fighting fund, and that scheme was hung up for at least seven months, during which there might be happenings of serious import. An address would be given by Mr. E. B. Turner, who had long been a convinced trade unionist, and afterwards he would invite questions and comments.

Mr. E. B. Turner, in the course of his well-delivered speech, said some of his hearers might not think a learned profession was the proper sort of body to form a trade union, but careful consideration had convinced him that under the changed conditions in which the profession found itself trade unionism was a practical necessity. Some people had been so foolish as to say—and others even more foolish to write—that the fight for the dignity and emoluments of the profession was now over, and all that remained was to sit down and make the best—or worst—of it. It was an unfortunate thing to say at the present time, because the whole of the relations of the medical profession to those patients who belonged to the industrial classes would before long be cast into the melting-pot, whichever political party might happen to be in power. Consideration was even now being given to the question of the provision of medical attendance to uninsured persons and to the dependents of those who were at present insured. The profession ought, therefore, to take warning from the past and be prepared for the future. In 1915 the extra two shillings and sixpence offered by the Chancellor would come to an end, and in that year there would probably be new legislation and amending Acts. A further important factor was the solvency or otherwise of approved societies. Those societies were finding, under the operations of the Act, what they considered an abnormal, but what was really only a normal, rate of illness, considering what bad lives many of the members were; and sick-pay was greatly crippling their resources. And even the larger societies were exercising the strictest supervision over their expenditure in order to keep within the bounds of actuarial safety. If some of them were likely to come to grief there would arise the allegation that the doctors were being paid too much and were doing too little for it, and consequently there would be an effort to reduce the remuneration. Such relationship came home to every doctor whose practice touched the industrial classes. There must be an adequate fund for the propaganda. One of the chief reasons the profession came to grief before was that the money behind them was not sufficient. There was then a fund, guaranteed by members of the profession, and vested in trustees appointed by the British Medical Association. It never totalled more than £137,000. Even if members had stood out and it had come to a fight, he doubted whether the fund could have been used effectually. And in the case of an action at law, which turned against the British Medical Association, possibly the reserve and the property of that Association could have been drawn upon for the purpose. Wherefore it was plain that if there was to be a fighting fund it must be safe, and the only way to ensure that was to fight by means of the fund of a trade union. In this country only two institutions were above the law—one was the King individually, and the other the trade unions, collectively and individually. The last few weeks furnished instances of the straining of the law to help trade unionists. The ideal would be for the British Medical Association, with its 24,000 members, to become a trade union; it could then carry out the scientific work of the profession on one side, and the fighting, the trade union work, on the other. But when that project was discussed, it was found that the legal difficulties were such as to be practically insuperable. But he did not want a trade union which would be pulling against the British Medical Association, but which would work in harmony with it and along parallel lines. Even the present potential fund of the Guild would probably be safer than the British Medical Association funds for fighting purposes. Whether it was possible to proceed against the individuals in trade unions was a matter under discussion, but it was clear that the funds of such union as such could not be drawn upon for the purpose. Further, if the profession wanted to get anything done in Parliament, it must, and ought, to have a voice in Parliament which should speak for the profession, and be independent of party. Those of the medical profession now in the House subordinated the interests of their profession to those of party, and he did not blame them for that, for they were sent there as party men. A representative of the profession could possibly be sent to the House from Marylebone. He hoped it would be clearly seen that this matter appealed not to any one section of the profession, but to the whole of it, and especially those whose work lay among the industrial classes. Such a trade union was the more needed as certain sections of politicians considered that the best way of looking after the health of the community would be an absolutely State service, including everybody, from the humblest practitioner to the senior consultant. He looked upon such a thing as most injurious, both to the profession and to the health of the public. However, the profession, properly organised, could put an effective stop on that. He hoped the profession would have a very strong and effectual trade union, embracing the medical men of the whole kingdom, and work on parallel lines and in harmony with the British Medical Association.

Dr. Boclet said the apathy of the profession on matters concerning its own defence was appalling; and it had resulted in the doctors being humiliated in the eyes of the public. He appealed for a united front, so that the profession could stand or fall together.

Dr. Tompkins said the British Medical Association had been blamed for its failure, and certainly one or two members of the Council deserted them in the time of need. But it must be remembered that the Association consisted of the unit members of the profession, who did not even, as a body, try to get together a decent fighting fund by giving two or three pounds each. The reason the trade-unions of the country had achieved such ascendancy was that the units had a personal interest in the struggles of their particular trade: the men did not do much speaking on platforms, but they met on leaving work and discussed questions. The British Medical Association was the largest body and the oldest, and it was the fault of members of the profession if it had not stood them in good stead in the past. He still thought it was to that Association the practitioner should turn, and he was glad to hear Mr. Turner say he hoped the Guild would work in harmony with the older and larger body. It would be well if the British Medical Association could hold the strings of the other societies, instead of the opposition implied in the multiplication of independent bodies.

Dr. Raiment (General Secretary) said a resolution would be submitted asking the British Medical Association to recognise the Guild as an auxiliary body, showing that the feeling and policy of the executive was not antagonistic to the older body. The Guild was registered in July of this year, and if for any purpose they wished to plead Section 4 of the Trades Disputes Act, it was not a matter of argument whether the Guild was a trade-union. Trade-unions possessed certain definite legal immunities and privileges. The funds of the Union, by the Trades Disputes Act of 1906, were protected from actions for libel, slander, actions in restraint of trade, acts of conspiracy, or tortious acts, the latter having been defined as anything from pocket-picking to manslaughter. The union was above the law in those respects. The British Medical Association could not act in restraint of trade, as shown by the recent action, The Marquis of Zetland *v.* The British Medical Association. If the Marquis of Zetland should succeed, it would not be possible for the *British Medical Journal* any longer to continue the useful work it had been carrying on for many years in issuing warning notices in the case of barred appointments. The action had certainly come at a most opportune moment to cause the profession to realise the truth of what the Guild had been preaching during the past few months. Great progress had been made at Salford, where some 95 per cent. of the practitioners had joined the Guild, and the branches at Sheffield, Leeds, Manchester, Oldham, Rochdale, Plymouth, S. Wales, Forest of Dean and along the South Coast were rapidly increasing in membership. In the British Medical Association the Guarantee Fund was raised by voluntary effort, and the same men were found to be giving each time. The Guild's method was to raise levies which, unless he could show good cause to the contrary, must be paid by each member or that member must resign; and the amount of such levies, in any year, had been limited to £20; but it was not expected that any such sum would be asked.

Dr. BURNHILL advocated the objects of the Guild, and thought the British Medical Association could be a purely academic body, the Guild looking after the material side.

Dr. TOWNSEND proposed "That this meeting of practitioners, having heard Mr. E. B. Turner, and being convinced of the necessity of a trades-union for the profession, pledges itself to support the National Medical Guild, and to use every legitimate means to compel the British Medical Association to recognise the Guild as an auxiliary body."

Dr. RAIMENT seconded, and it was carried, three voting against.

Mr. Turner was cordially thanked for his address, and in his acknowledgment he recommended British medical men to emulate their German confreres at the present moment in their efforts to secure what they felt they were entitled to.

ROYAL COMMISSION ON VENEREAL DISEASES.

At the eighth meeting of the Royal Commitssion on Venereal Disease, evidence was given by Sir William Thompson, Registrar-General for Ireland. He said that as a cause of death venereal diseases played a relatively small part in Ireland. The death-rate from syphilis and allied diseases was 0.78 per 10,000 of the population, whereas the figures for tuberculosis at the head of the list were 21.52 per 10,000.

Compared with previous years, the deaths from syphilis and general paralysis of the insane appear to show a tendency to increase, but Sir William Thompson thought that much of the increase was more apparent than real, and was due to the more careful recording of deaths. The greater part of the deaths from venereal diseases occurred in the two cities Dublin and Belfast. In Dublin the figures were abnormally high, the death-rates from syphilis and general paralysis of the insane being about twice those of London. On the whole, the incidence of venereal disases in Ireland was very must lower than in the rest of the United Kingdom; the syphilis death-rate was only that of England and Wales, while with regard to infant mortality the number of deaths due to syphilis per 1,000 births in the three Kingdoms were: England and Wales, 1.29; Scotland, 1.4; Ireland, 0.59.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Dec. 20th, 1913.

PULMONARY EMPHYSEMA.

PULMONARY EMPHYSEMA, says Dr. Rosenthal in the *Monde Médical,* may be considered as observed in the adult and in children.

In the adult it is a chronic affection leading to grave complications as it progresses.

Treatment endeavours to arrest its progress, but cannot pretend to restitution *ad integrum.*

In children emphysema is observed in the course of pulmonary affections as capillary bronchitis, whooping cough. Here a complete cure may be obtained by intelligent treatment, for the anatomical lesions are much less pronounced. It is simply a question of distension of the alveoli without breaking down of the walls.

The causes of emphysema are numerous: Heredity, neuro-arthritism, acute pulmonary affections, and, more especially, bronchitis, dyspnœa, violent efforts, cough, etc. One of the chief causes of emphysema is asthma; all asthmatic persons became emphysematous.

The palliative treatment of emphysema consists in iodides and arsenic:—

Iodide of Potassium,	3 gr.
Arseniate of Soda,	1 gr.
Water,	10 oz.

One or two tablespoonfuls a day, half-an-hour before meals. Dujardin frequently prescribed tincture of Lobelia, and Saint-Phillippe gives the preference in the child to iodide of arsenic:

Iodide of arsenic,	6 grs.
Water,	10 oz.

five to fifteen drops at meals.

Where there is reason to believe in the existence of tracheo-bronchial adenopathy, M. Hirty prescribes:

Metallic iodine,	2 gr.
Iodide of potassium,	½ dr.
Arseniate of soda,	1-5 gr.
Syrup of bitter orange,	6 oz.

a tablespoonful each morning.

However, these drugs cannot be prescribed indiscriminately; account must be taken of the ætiology. In arterio-sclerosis iodides will be freely prescribed; in stout persons arsenic will be avoided.

If pharmaceutical treatment has a certain recognised utility, it is much inferior to the practice of physiotherapy, which is really curative, especially in children.

A person suffering from emphysema, says Rosenthal, presents both lesions of the pulmonary parenchyma and respiratory troubles. Distension of the pulmonary alveoli with thinning of the walls and rupture of the elastic fibres characterise the lesion. Inspiration is brusque, expiration slow, difficult and incomplete. The thoracic cage is rigid, and at each inspiration the diaphragm lowers a little.

Against these troubles kinesitherapy has aim: To educate the rhythm of the respiration, to suppress the insufficiency of the diaphragm, to correct the rigidity of the thorax, to educate the expiration, etc. Such effects are obtained by different mechanical apparatus. Aerotherapy has also been employed with success.

Questions of hygiene, alimentation, climatology and mineral waters have a great importance in the prophylaxis and treatment of emphysema.

Patients suffering from emphysema are always very susceptible to atmospheric variations; they take cold for nothing. They should be inured to external reactions by cold lotions of the body or dry frictions with spirits of lavender. They should not take any alcoholic liquors, and should be very moderate in the use of carnine foods. Whenever possible they should spend the winter in a warm climate.

Cold in the head, laryngitis and bronchitis should be immediately treated.

As to the mineral stations, Mont Dore is the most frequently indicated; however, if bronchitis with suppuration is present Saint-Honoré, Eaux-Bonnes, Cauterets should be preferred. Where cardiac troubles exist, the carbo-gaseous baths of Royat are very useful.

As to complications that may be observed in emphysema, dyspnœa may present special characters: It comes on by attacks and appears to be independent of all bronchitis or congestion. It is best met with inhalations of nitrite of amyl, fumigations of nitre paper, acetic ether, thirty drops in a four-ounce mixture, taken by dessertspoonful every hour, inhalations of oxygen gas, or, better still, subcutaneous injections of this gas according to the method of Ramond.

Opium or morphine should be used sparingly.

Bromide of potassium,	3 dr.
Cherry laurel water,	3 dr.
Syrup of ether,	1 oz.
Water,	5 oz.

Two or three tablespoonfuls a day.

The heart will be sustained by sparteine, camphorated oil, caffein, digitalis, in small doses.

GERMANY.

Berlin, Dec. 20th, 1913.

At the Verein für Innere Medizin and Kinderheilkunde Hr. Magnus Levy communicated a note on the

SUBCUTANEOUS INFUSION OF SOLUTION OF BICARBONATE OF SODA.

He said that solution of sod. bicarb. in cases of diabetic coma could be given by the mouth, the bowel, subcutaneously, or into a vein. Usually the administration was either by subcutaneous infusion or transfusion into a vein. Unfortunately, however, when 4 per cent. solutions were made use of necroses had not unfrequently been seen to follow. If these were to be avoided, the solution should not be stronger than 3 per cent., and of this about a litre might be given at one time. He had had good results with his cases treated in this way. Sod. bic. was decomposed by allowing the solution to boil, but it could be produced again in the system by injecting carbonic acid.

Hr, Rosenthal said that amongst the cholera patients in Bulgaria saline injections were made in cholera coma, which was not unlike the coma of diabetes, and with good results. Out of 24 cases treated in this way 12 recovered.

Hr, Umber believed that the effect was more stimulating on the heart when the injections were made into a vein.

Hr. His suggested that the soda solutions should be kept in large ampullæ under pressure of carbonic acid with the necks hermetically sealed or rather melted together. This would prevent the decomposition of the sodium bicarbonate.

Hr. Kausch had seen good effects in surgical practice from intravenous injections of solutions of soda alone.

Hr. Hirschfeld considered Hr. Levy's proposal to be a distinct step in advance. In giving intravenous injections an excess of vascular pressure was set up that had injurious consequences.

Hr. Klemperer, on the other hand, did not think that the alkali treatment of diabetic coma had shown any material practical advantage. He himself had seen only transient improvements. In such cases he gave coffee and camphor also and infusions of grape sugar.

Hr. Ehrmann pointed out that intravenous infusions raised the blood pressure whilst subcutaneous ones did not.

At the Gesellschaft für Chirgurie Hr. Harzbecker showed a

MULTI-SUFFERER.

The patient was a shoemaker æt. 44. In the year 1887 he fell from a horse, and after the accident and in supposed association with it, he suffered repeatedly from attacks that resembled ileus. During a period of 18 years laparotomy was performed on him no less than 24 times, the first operation being in 1895 and performed by Geheimrat Rötter. He was again under Hr. Rötter's care in 1903, when colostomy was performed. Later on an artificial anus was made, and last of all an anastomosis between the cæcum and the sigmoid flexure. After that he underwent only conservative treatment, light baths, infusions into the sigmoid, physostygmine, and morphia. It was said that the light baths had done the most good.

The patient showed all the typical features of chronic interospasm. The mischief was undoubtedly in the peristalsis, and was entirely due to nervous causes. Whether the accident had any causal influence could not be said with certainty. The patient in the mean time was a psychopath, an alcoholic, and also a morphinist. It was to be hoped that the demonstration of the patient with its publicity would prevent any further useless laparotomies.

Hr. Sonnenberg observed that the patient had been in the Moabit Hospital five times. There he had been treated with moderate doses of morphia and with success.

Hr. Max Cohn showed a diapositive of the patient in which, however, nothing could be recognised showing a connection with any of the numerous operations that had been performed. Neither was anything visible by which the very bad adhesions met with could be recognised.

At the last meeting of the Medizinische Gesellschaft when the time came for the discussion on Professor Bumm's report on his experiences in the treatment of malignant diseases by thorium X, radium and the X-rays, the president announced that before the reading of the paper he had given instructions that the doors of the hall should be guarded and requested members of the society to divulge as little as possible of the proceedings to the lay press. Sufficient publicity and that of the proper kind would be afforded by the presence of the accredited reporters of the professional journals. It will probably have been noticed how very freely medical matters, especially as regards new methods of treatment, have been discussed in the lay press. It has been felt that this has been overdone and that the custom is eminently calculated to lead to abuses—of more than one kind. Hence the precautions mentioned.

UNITED STATES OF AMERICA.

New York, Dec. 1st, 1913.

CLINICAL CONGRESS OF SURGEONS.

(*Continued from issue of December 10th.*)

The feature of the meeting was the great attention paid to the

Campaign against Cancer.

As stated in The Medical Press and Circular, in the account given of the meeting of the Clinical Congress in New York in November, 1912, and again of the meeting of the Canadian Medical Association in June of this year, a campaign under the auspices of the American medical profession is being waged vigorously against cancer. Its results up to the present and the prospects of a successful issue were made prominent matters for discussion at the Chicago meeting.

On Wednesday, November 12th, Professor Krönig, of Freiburg, Germany, dealt with the radiotherapeutic treatment of

Benign and Malignant Tumours.

He concluded that so far as the investigations of himself and colleagues up to date were concerned, they had not succeeded by means of the *technique* employed in curing a single case of metastatic carcinoma. It was quite possible to produce remarkable retrogressions and checking of the carcinomatous metastases by means of intense radiation of Roentgen-rays and radium, but in all cases up to the present the carcinoma had later on spread further. They could not say they had saved a single patient. In the second group the majority of cases were at the present time impossible of cure, in spite of any known Roentgen-ray and mesothorium activity.

Dr. Howard A. Kelly, of Baltimore, said that he had used radium in 366 cases, of which 188 were malignant growths. He had treated forty cases of cancer of the lower part of the uterus, where the disease was apt to spread rapidly, and the cases were considered hopelessly advanced and inoperable, and in three of them, after extensive operation, radium was used. If the usual methods had been followed a speedy recurrence would have taken place without question. In these three instances there had been no recurrence and health had been fully restored. Dr. Kelly told of a few other cases of malignant disease in which the employment of radium had been followed with most satisfactory results. He stated as his opinion that if a more abundant supply of radium were available its use for superficial cancer would yield better results than surgery. It would cure cases of cancer of the nose, lip, etc., where surgery would only mutilate.

On Thursday, November 13th, the report of the Cancer Campaign Committee was read. Dr. Thomas L. Cullen, of the Johns Hopkins University Medical School, Baltimore, one of the prime movers in the Campaign, said in part when people once understood the nature of cancer they would gladly avail themselves of surgical aid. In the past decades attempts to instruct the physicians alone had not produced any decisive results. Hence they had to go to the people at large through the newspapers and magazines. Many popular articles had already appeared. The Press had responded nobly to their appeal. As a result patients were coming earlier. Still, there was need for further dissemination of knowledge by means of lectures on hygiene in women's clubs, factories and elsewhere. Better records had to be kept, hospital statistics had to be carefully analysed so that accurate deductions could be drawn from them; they must have surgical pathologists to aid in diagnosis. Thorough operations must be insisted upon as soon as the diagnosis of cancer had been made. All modern methods of recording data must be utilised in hospitals. Patients who had been operated upon must be followed up and the results recorded.

Cancer of the Uterus

was one of the most frequent forms of cancer in women. The first symptom of cancer of the uterus was bleeding, and as the disease progressed and parts of the cancer broke down, the discharge became offensive. Cancer of the neck of the uterus was the most common form and could be readily detected by the use of simple instruments. Cancer of the body of the uterus could not be seen and could only be definitely determined by scraping away some of the material and examining this with the microscope. The material removed was suitably hardened and shavings about 1-500th of an inch thick were made. and these were stained and examined with the microscope. The pattern of cancer was totally different from that found in health, and the expert with the microscope could usually tell with absolute certainty whether the disease was cancer or not. In past years few cases of cancer of the womb had been cured. Now from 20 to 25 per cent. of those suffering from cancer of the neck of the uterus who were operated on, were permanently relieved. The results following operations for cancer of the body of the uterus were still more comforting, at least two-thirds being permanently cured. Cancer of the uterus was most common between the 30th and 50th years, but had occurred in early womanhood and might also attack the aged. Any woman with bleeding that could not be definitely explained ought to be examined at once, and any patient having much bleeding at the time when "change of life" occurred ought to seek medical aid forthwith. The bleeding might be due to cancer or might be caused by some simple ailment. When women realised what splendid permanent results might be obtained by early operation and fully appreciated the necessity of finding out exactly what was the matter with them, instead of procrastinating until the disease was far advanced, then the percentage of permanent cures would be greatly increased. Mr. Samuel Hopkins Adams, of New York, the lay writer who has been chiefly instrumental in forwarding the Campaign amongst the community at large, said that much could be done in health education of the public, whether in cancer, tuberculosis or the venereal plagues, or in epidemic diseases, by lectures, but more could be accomplished by the magazines. The universal agency, however, of popular education was the daily press. Between that agency of enlightenment and the medical profession there had been raised a barrier fraught with difficulty, the barrier of the unwritten law of the profession, which said to the doctor: "Thou shalt not appear in print." The daily paper, with all its sins, was the one agency by which the medical profession could impart immediate, positive, and direct universal education, a saturated solution of enlightenment. Nothing else would do it. There was no sacred reticence required of a doctor other than the reticence that guards the privacy of his patient. The time had come when the obsolete ban of silence should be lifted and the propaganda should go on through the agency best fitted to spread it, the daily newspapers.

Dr. Edward Reynolds, of Boston, discussing the question of publicity and education by means of the American Society for the Control of Cancer, said in part, after referring to the essential importance of diagnosing cancer in its early stage, that individually the members of the society did their best to publish to the world the fact, but collectively and as a profession nothing had yet been done. Little influence could be exerted upon the over-conservative, the timid, and the other weak and halting members of the profession; but our patients, the great lay public, had a right to demand that every member of the profession should be forced to do his duty in this direction. As yet the profession had not had the organisation, the money, nor the trained workers which were essential to success. The profession was more than ready to give its time and its trained ability to the work, but the profession formed neither a large nor, as a whole, an affluent percentage of the community. The money for any such widespread organisation must come from the numerous and more wealthy laity, for whose benefit this movement was being inaugurated. The American Society for the Control of Cancer was a body which was composed of prominent members of the profession and of influential members of the laiety. It was actively at work in perfecting a widespread organisation of national scope for the prosecution of the campaign. It planned to work in co-operation with all the existing organisations in the study of cancer and in promotion of the necessary publicity of all the points on which we already had assured knowledge. It asked the sympathy and effective aid of every member of the profession, and of every interested layman and laywoman.

(*To be concluded.*)

NOTES FROM THE AUSTRIAN TYROL,

In the course of travel one hears a good deal of Innsbruck, the principal city of the Tyrol, and those who have had the good fortune to visit these parts pronounce it without hesitation to be one of the most enchanting resorts whereto those contemplating a Continental tour can turn their steps.

Fortunately, it is not yet overrun by holiday crowds of noisy tourists as are the Swiss resorts in winter. Here all is calm and brilliant as the sun, which appears to shine in the utter absence of fog throughout the day. When I first made acquaintance with Innsbruck in somewhat shattered health some ten years since, I was amazed at the beauty of its surroundings and the picturesqueness of the town: amazed also that it was so little known to English travellers. Times have now changed here as elsewhere. The majority of visitors appear to be of English or American nationality, with a large consignment of those whose military or civil duties have chanced in India or other sub-tropical countries and who have come here to recruit their health. The Hotel Tirol likewise, at which I then stayed and am now staying, has increased its accommodation of necessity and is now a magnificent building, under the same genial control of Mr. Carl Landsee. It is not possible that the beauties of this extensive country can be realised in a sojourn of two or three days. Weeks, if not months, can be happily spent here. The excursions are numerous and unique, and with the present-day craze for motoring, long distances can be negotiated through the most glorious Alpine scenery to be found anywhere in Europe. But fortunately these parts are not as yet overrun by the hooting motor, and sleighing can be indulged in with impunity. As a health resort Innsbruck can fully hold it own. The air is tonic, dry, invigorating; free from sudden changes of temperature. No cold winds are felt here, as it is situated 2,000 feet above sea level in the centre of a basin whose sides are snow-covered mountains rising from 7,000 to 8,000 feet, which protect it from the north and east, whilst the mountain sides act as a colossal reflector of the sun, which sheds its radiant warmth through the motionless air of the valley during the day, whilst the nights are invariably cold and dry.

Innsbruck, too, is not an out-of-the-way region. Few cities have more advantages; it boasts of a University, with other excellent educational establishments, first-class train service, with through trains from

Paris and Brussels to Vienna, and from Berlin and Munich to Rome, thereby giving unusual facilities for travel. To this glorious Tyrol, picturesque to a degree, with health and pleasure resorts adapted to the majority of humanity, we journey over the beautiful Brenner Pass, enveloped at noontide in a mantle of white velvety snow, and at the sunrise and sunset hours as in a garment of many colours; for with the rising and setting of the Tyrolean sun the hills present a panoramic view of unique tints, giving us a tableau of oriental colourings yet to be appreciated by the artists of our day. These hills and valleys are enlivened by the gay sleighs drawn by handsome horses which evidently enjoy the lively pace, and each equipage exchanges with passers-by salutes in a variety of dialects. "Isn't this too lovely for words?" is an English and American exclamation often heard from their occupants as we drive rapidly toward this "Ideal resort of the Tyrol." It is indeed a fascinating city, bright with cleanliness and abundant sunshine; having every imaginable winter amusement—skating tobogganing, ski-promenades, curling, military music, balls, good concerts, theatre, museum and library, English chaplain and daily church services, a British Vice-Consulate, and last, but not least, excellent hotels at very moderate terms.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

City Slums and Town Planning.

Sir John Stirling Maxwell, Bart., at a recent meeting held at Glasgow University under the auspices of the School of Social Study and Training, delivered a lecture on Garden Cities and Town Planning. Upon the latter branch of his subject he said that to pull down slums and turn out the inhabitants to go where they could was only to move on the problem, not to cure it In Liverpool, where a slum population of some thousands had really been rehoused, where every family turned out had been put into a new house under sensible superintendence, the result had been the disappearance of the slums. Though there had been a heavy direct loss on the undertaking, the hardheaded business men who had seen it through were convinced that indirectly the ratepayers had gained by diminution in the poor law, public health and police charges. In dealing with the other branch of the subject, Sir John referred to the first garden suburb in Glasgow, at Westerton. Thirty-five houses were now occupied. It was a gentle southerly slope, with a fine view over the Clyde Valley and the shelter of woods to the north, and was quite an ideal site.

The Research Defence Society held a public meeting of its Glasgow Branch on 19th inst. The object of the Society is to make generally known the facts as to experiments on animals in this country, and the regulations under which they are conducted. Lord Lamington presided, and among the speakers were Professor G. Sims Woodhead, M.D., and the Rev. Hubert Simpson. Questions were allowed from the audience, but no discussion. Much interest was evinced, and an overflow meeting was arranged under the presidency of Sir Hector Cameron, M.D.

The Very Rev. Principal George Adam Smith, in opening for the second day the

Aberdeen Red Cross and Health Service Exhibition,

spoke of the educational value of the exhibition. The work of the Red Cross, he said, was for times of peace as well as for times of war. They were all proud of what the British Society had done during the Balkan War. No fewer than ten units were sent out, comprising 220 persons, and they were the means of relieving over 16,000 cases. That was a record of which they might be proud, because the work was achieved at a great distance from the Society's own base and among a foreign people, and done with the purest motives of philanthropy. They had all read of the assistance and relief of the various national Red Cross Societies in great national disasters, such as floods, earthquakes and fires.

The Highlands and Islands Medical Service.

A circular has recently been issued by the Highlands and Islands Medical Service Board to School Boards, parish councils, etc., with reference to medical service administration in the Highlands. A conference of representatives of a large number of School Boards, etc., took place at Logierait on 18th inst., when an interesting discussion resulted. The district under consideration was the Highland district of Perthshire. Among other resolutions come to, it was agreed to represent that a uniform fee should be arranged for patients outside a ten miles radius, in cases where the income was £2 and under per week, to be supplemented by a grant from the Medical Service Board.

BELFAST.

Scarlet Fever.

A severe epidemic of scarlet fever is at present raging in Belfast. There are at present in the available infectious hospitals (Purdysburn Fever Hospital and the fever hospital in connection with the Belfast Union) about 500 cases. Last week there were 89 new cases notified. Some of the cases are of the virulent type, and the death-rate in hospital up to the present is 6 per cent, a figure much above the average.

Belfast Local Medical Committee.

At a meeting of practitioners residing in the County Borough of Belfast held on the 18th inst., the work of the first Local Medical Committee was reviewed and the new committee was elected. The late committee was elected in April, 1912, and held office for over a year and a half. It consisted of 60 members, representing every interest in the profession. Twenty-four meetings were held, the average attendance being 37. In connection with the work of the committee, there were eight meetings which the whole profession in the borough was summoned to attend, as the business was on these occasions of a specially important character. Sir John Byers, the Chairman, was only absent on two occasions. There were three Sub-committees—viz., for Finance, Complaints, and Tuberculosis. These sub-committees met frequently. The Tuberculosis Sub-committee had several conferences with the Public Health Committee of the City Corporation in reference to their tuberculosis scheme. Nothing definite has yet been arranged, but it is probable that £5,500 will be available for distribution among general practitioners for domiciliary work. There were several conferences with the Local Insurance Committee, and the Local Medical Committee of Belfast was the first committee in Ireland to arrange with the Health Commission to secure domiciliary treatment at a liberal rate of remuneration. The committee sent a representative to the Irish Medical Committee.

There has been much correspondence with the Friendly Societies, but up to the present no satisfactory arrangement has been come to with these bodies.

Dr. T. A. Davidson, the Secretary of the Local Medical Committee, has spared nothing in endeavouring to organise the work of the committee, and to him are due the thanks of the entire profession in Belfast for his arduous labours on their behalf.

It is said that Dr. Dubard, of Dijon, has invented an antiseptic varnish, which is to supersede the use of operating gloves by surgeons. It is composed of a mixture of essence of juniper berries and an alcoholised solution of menthol. On evaporation, a protecting and antiseptic varnish is left behind.

Society of Apothecaries of London.

The following candidates, having passed the necessary examinations, December, 1913, have been awarded the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery and Midwifery:—A. C. O. Brown, H. V. Capon, R. B. F. Fraser, J. de Silva, and J. E. Taylor.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE DISCOVERY OF THE LIFE-CYCLE OF THE ORGANISM OF SYPHILIS.

To the Editor of The Medical Press and Circular.

Sir,—The leading article in your issue of the 17th inst. calls for some comment.

The valuable recent discoveries were led up to by one of the observers finding, as did many others, that salvarsan, though it causes the spirochætes to disappear, is not the one-dose sterilising drug that its gifted inventor hoped it would prove to be.

The inference was that the protozoon passed through stages other than the spiral form; stages in which it was either inaccessible to or invulnerable against salvarsan.

Many years ago, from the natural history of the disease, its long latent period, its marked and fairly regular stages, and the varied yet graduated character of the lesions that usually mark its course, I deduced the *causa causans* of syphilis to be probably a protozoon. After having familiarised myself with the commoner pathogenic protozoa in animals and man, I looked for and found protozoa in the cells of the swollen epidermal margin of a rapidly spreading secondary ulcer. I am sure that no series of cell-forms put forward as the life-cycle of the protozoon of syphilis can be complete if it does not include the bodies that I demonstrated in 1894 (*a*) and also those I found later in a tertiary lesion and described in 1907 (*b*).

It may be noted that my first demonstration of protozoa in syphilis was made more than ten years before the spirochæte phase was described by the late Fritz Schaudinn in 1905.

I am, Sir, yours truly,
J. Jackson Clarke.

18 Portland Place, W.
19th December, 1913.

To the Editor of The Medical Press and Circular.

Sir,—It is, I think, certain that I am expressing the voice of a great number of your readers when I thank you for your leader of December 17th on the above subject. It is entirely luminous as regards the scientific aspect of the question, and it seems to demonstrate conclusively the claim of Mr. McDonagh to the credit of having first made the discovery of the life-cycle of the organism of syphilis. The controversy closely resembles that which took place over the discovery of the organism of sleeping sickness. Such disputes are, of course, supremely important to the parties immediately engaged; and the principles involved and the ethical questions raised vitally concern all scientific workers. If such disputes become more common it will be necessary for investigators to register and verify every step of their progress towards the establishment of a new fact, and it will be desirable to formulate some method whereby this may become feasible. It is, of course, occasionally the case that two workers approaching a problem from the same or even a different starting-point, and having no communication with one another throughout, arrive simultaneously at the same conclusion or make the same discovery. And it seems more probable that such a coincidence may occur more frequently when men are constantly meeting, discussing a problem, and mutually explaining their aims and methods. It is interesting to note that there is so much human nature in scientific men. It might be thought that their training and their work would produce and maintain for them a cold philosophical calm which would render them incapable of the sentiments of envy and uncharitableness which influence or dominate the minds of the bulk of common men.

I am Sir, yours truly,
A Working Pathologist.

December 19th, 1913.

THE QUESTION OF REFORM OF THE B.M.A.

To the Editor of The Medical Press and Circular.

Sir,—I quite agree that it is necessary at times to be frankly and apparently brutally outspoken in order to save a sick man; but we must be quite certain that such treatment is not fraught with danger to the patient. The reason why I did not analyse the issues raised as to the need of domestic and financial reform was that by so doing I should not have advanced the solution of the question in the slightest degree. May I refer to the concluding sentence of a letter I wrote to your journal on February 18th of this year:—"Let us, if we can, make practical suggestions for increasing the Association's financial stability, and I am confident that suggestions will be gratefully acknowledged and acted upon." This is the whole crux of the matter. Let us not attack the Association, but show it a better way. I entirely accept your explanation that your remarks were made in a spirit of friendly candour, as I have always regarded your journal as noted for its fairness in dealing with matters affecting the welfare of the profession. Your correspondent, "An Obscure Practitioner," has hit the right nail on the head when he attributes any shortcomings of the Association to the apathy of the majority of its members. With regard to the *British Medical Journal*, I should think that the greatest difficulty to be faced by the Editor in any attempt to cut down the size of the *Journal* would be to decide what part of it should be omitted. Some readers read the surgical papers, others the medical, still others the epitome. Cut down any of these, and at once the readers thereof would cry out, and probably write letters of indignation, pointing out that the very part of the *Journal* of importance had been omitted. With regard to its weight, doubtless it would be much lighter if all advertisements were omitted. If this were done, then the result would be not only serious financial loss, but great inconvenience to many of its readers, who, like myself, often refer to the advertisement columns to find an address or look up a preparation.

Now "the small meeting" referred to by "An Obscure Practitioner" probably represented the active members of the division—those who follow the work of the Association most closely. I sincerely trust that the prophecy of "An Obscure Member" that a very large proportion of the members will resign will prove false. To sum up the matter, we are all anxious to do our best for the Association. Then let us suggest methods of improving its financial position. Any suggestions which any of your readers will make I am confident will be gratefully acknowledged and, if practicable, acted upon. Then we shall not read of "some hazy future," but of a brighter present. Let us remember that so far as the apathy of the majority goes, we can only arouse interest by directly threatening their bread and butter. This the Insurance Bill achieved in a marvellous manner; but bad habits are overcome with difficulty, and the majority of the members of the Association again slumber.

I am, Sir, yours truly,
S. T. Ross.

Monkhams, Bedford.
December 17th, 1913.

FAITH HEALING AT UNIVERSITY COLLEGE.

To the Editor of The Medical Press and Circular.

Sir,—My attention has been drawn to "Scrutator's" letter in your issue of the 17th inst.

He wrongly concludes that I did not criticise Lord Sandwich's speech. I did strongly raise an objection to his remarks at the meeting, but his lordship's speech made good copy for the newspapers, and consequently the reports of the medical speakers were greatly abbreviated.

I was neither a member of the Committee of the

(*a*) "Transactions of the Pathological Society," 1895.

(*b*) "Transactions of the Royal Medico-Chirurgical Society," 1907. This subject is dealt with in the writer's "Protozoa and Disease," part ii., chapter viii.

Psycho-Medical Clinic, nor was I in any way connected with the movement. My presence at the meeting was due to a request to say a few words in support of the Clinic and the work that they hoped to carry out, and this I was glad to do, knowing that the Clinic was starting under the auspices of several well-known physicians and psychologists.

That the Chairman should have taken advantage of his position to enlarge upon his own personal power was disastrous to the cause he sought to support, especially as the newspaper reporters selected his speech for publication.

To withdraw their names and support was the only professional means available for the various medical men associated with the movement, and this they did at the earliest moment. Therefore, as medical objections to the Chairman's remarks were raised at the meeting, and as all the physicians connected with the Clinic withdrew their support immediately after, I fail to see what more could be done to prove to the public that Lord Sandwich's statements were not in accord with medical opinion.

I am, Sir, yours truly,

Maurice Craig.

54 Welbeck Street,
Cavendish Square, W.
December 19th, 1913.

OBITUARY.

DR. T. B. YOUNG, OF SUNDERLAND.

We regret to record the death, after a brief illness, of Dr. Thomas Beveridge Young, which occurred on the 10th inst., at his residence, 122, Herrington Street, Sunderland. The deceased, who was forty-four years of age, was a Scotsman, being born near Kilwinning, Ayrshire. He studied at the Royal Infirmary, Glasgow, and took the L.R.C.P. and S.Edin., L.F.P.S Glasg. After being at Newcastle-upon-Tyne for some time he came to Sunderland as assistant to Dr. Cunningham, with whom he stayed for five years, leaving to establish a practice at 122 Herrington Street 18 years ago. His recognised ability and genial manner quickly gained him a large practice, and he became one of the most popular medical men in the town, gaining a very large practice of an exacting character. He was frequently called as an expert witness in workmen's compensation cases at the Sunderland County Court. He first entered public life on February 25th, 1910, when he was elected a member of the Town Council for the Hendon Ward to fill the vacancy caused by the death of Councillor Thomas Summerbell. His professional knowledge was of great assistance to the Corporation, and as a member of the Health, Watch, Building, Cemeteries and Tramways Committees he rendered valuable service. He was a Liberal and a member of the Sunderland Liberal Club, and was also a well-known Freemason, being associated with the St. John's Lodge. Dr. Young married Miss Smith, of Hendon, and his widow and family of six children (five sons and one daughter), the eldest of whom is 19 years of age, are left to mourn his demise. Of remarkable geniality of temper and of great kindness of heart, he enjoyed a wide circle of friends, and was respected by none more than his patients.

LITERARY NOTES.

The seventh volume of "Daily Mirror Reflections," containing over one hundred cartoons from the pen of Mr. W. R. Haselden is pre-eminently one to place upon the waiting-room table. The subjects depicted are all topical, and several of them, notably those on "Weeping as a Cure" and the "Open-air Breakfast," have considerable medical interest.

* * *

The last two issues of the *Prescriber* for November and December contain much that is of interest to the practitioner. The first of these deals with tuberculin and the methods of its administration, together with a concise review of tuberculin therapy. A critical summary of the more recent works on tuberculin treatment is also given. The second is occupied with original articles, some useful prescribing notes, and a review of therapeutic progress. This up-to-date little monthly is published at 137 George Street, Edinburgh.

* * *

The twenty-fifth anniversary number of the *British Journal of Dermatology* was issued last month. It contains three interesting retrospects by Sir Malcolm Morris, K.C.V.O., Dr. J. J. Pringle, and Dr. J. Galloway, three former editors of the *Journal*, the former of whom compares the "refined and realistic half-tone illustrations which now at once elucidate its teachings and embellish its pages," which are certainly to be preferred "to the crude chromo-lithographs which stare one in the face as one turns over the leaves of the first volume." To be of any use at all for illustrating dermatological affections, photographs, plain or produced by the colour process, are alone permissible.

MEDICAL NEWS & PASS LISTS.

Health Exhibition at Aberdeen.

An exhibition of Red Cross and National Health Service work, under the auspices of the British Red Cross Society, was formally opened at Aberdeen last week by the Earl of Aberdeen. There are sections devoted to Red Cross work, infant welfare, food and cookery, nursing, school hygiene, personal hygiene, and housing, with lectures and entertainments and numerous demonstrations, while the cinematograph is employed to illustrate. Lord Provost Maitland presided. In opening the exhibition, Lord Aberdeen said the scheme was only formulated in October, but from the first there had been a magnificent display of steady energy, zeal, and co-operation, and he knew that the exhibition would in its result prove worthy of all that trouble. He read the following telegram from Lady Aberdeen, who, he explained was detained at Dublin in connection with the transference of the sanatorium to the municipality there: "The keynote of the exhibition is intended to be a demonstration of the possibilities of Red Cross and all other health work needing co-operation between official and voluntary workers. Please convey my warmest greetings and regrets at being absent." Professor W. H. Thomson (Dublin) in the evening gave the first of the series of health lectures.

The Hospital Sunday Fund.

The annual meeting of the constituents of the Metropolitan Hospital Sunday Fund was held at the Mansion House last week, Alderman Sir J. Bell presiding. In their report the Council stated that this year's collection, the 41st, resulted in a total of £64,991 15s. 1d., a decrease of £2,981 compared with the previous year. In the various places of worship £28,434 was collected, being £7,432 less than in 1912. A portion of this decrease was accounted for by the discontinuance of the practice of adding donations to the amount of about £4,000 to the collection at St. Paul's Cathedral. The sum credited to the cathedral in 1913 (£287 15s. 3d.) was the amount actually collected plus two donations added by request of the donors. The net falling off in the church collections was therefore about £3,000.

It was moved that the date of the next Hospital Sunday be June 14th, 1914, and this was agreed to.

A motion to submit to the consideration of the Council a resolution declaring that "no grant be given to any hospital having a vivisection laboratory attached to its medical school on the ground that the practice of vivisection is directly opposed to the teaching of Christ" was rejected by a large majority.

Fatal Accident to a Medical Man.

At the inquest last week on Dr. Wm. Chas. O'Donoghue, of Liverpool, who met with a terrible death in a Cheshire lines train at Flixton, evidence was given that he was taken ill on the way to Liverpool from Manchester, and when he put his head out of the window was struck by a passing train.

Supt. Hogg, of the Cheshire lines, said the doctor was struck by the handle of a van door of a passing train which by some means had been left open.

The jury returned a verdict of "Accidental death," and found there had been negligence on the part of railway servants in leaving the door open.

The National University of Ireland.

The returns of the matriculation examinations, summer and autumn, 1913, show that 736 candidates entered for the examinations; of these 457 passed and became matriculated students of the University. In addition, there have been matriculated on the results of the intermediate senior grade and other public examinations, 95 students, making a total of 552 students matriculated in the year 1913 to date, December 16th.

University of London.

The following have passed the M.D. Examination for Internal and External Students:—

Medicine.—*T. Beaton, B.S., Charing Cross Hosp.; W. E. Burrows, B.S., B.Sc., Middlesex Hosp.; Hazel H. Cuthbert, B.S., London (R.F.H.) Sch. of Med. for Women; R. R. Elworthy, B.S., Westminster Hosp.; W. C. Fowler, B.S., Univ. Coll. Hosp.; G. Hadfield, B.S. (University Medal), St. Bartholomew's; R. H. H. Jolly, B.S., Charing Cross Hosp.; Cicely M. Peake, B.S., London Sch. of Med. for Women; E. E. A. T. Rigg, B.S., H. D. Rollinson, B.S., and A. R. Spencer, Univ. Coll. Hosp.; G. E. S. Ward, B.S., Middlesex Hosp.; G. R. Ward, B.S., Westminster Hosp.

Mental Diseases and Psychology.—R. Brown, B.S., Univ. Coll. and Westminster Hosps.; A. A. W. Petrie, B.S., Univ. of Edin.

Midwifery and Diseases of Women.—D. J. Harries, B.S., Univ. Coll. Hosp.; R. Larkin, Guy's; A. A. Straton, B.S. (University Medal), St. Mary's.

Tropical Medicine.—R. Kelsall, B.S. (University Medal), Manchester Univ. and London Sch. of Trop. Med.

*Obtained the number of marks qualifying for the University Medal.

University of Oxford.

The following have satisfied the examiners for the Diploma in Public Health:—

Part II.—C. H. Browning, R. H. Deans, E. T. H. Lea, T. J. Mackie, and H. K. Ward.

Part I.—Effie G. Brander, C. H. Browning, N. A. Coward, W. Gilmour, C. B. Gratte, F. R. M. Heggs, H. L. Hopkins, E. T. H. Lea, T. J. Mackie, A. B. Mitchell, J. Powell, E. Ll. N. Rhodes, H. W. White, and J. H. Wood.

University of Cambridge.

At a Congregation on December 19th the following degrees were conferred:—

M.C.—K. J. A. Davis, King's; R. M. Vick, Jesus.

M.B. and B.C.—H. Y. M. Mansfield, Emmanuel.

B.C.—J. H. Newmarch, Pembroke; T. H. Oliver, Caius.

University of Liverpool.

The following have qualified for the diploma in Tripical Medicine:—C. M. Austin, M.B. Ch.B., S. S. Banker, L.M. and S., L.R.C.P., M. Carrasco, L.M. and S., J. M. Clark, M.B., B.Ch., E. C. Hepper, L.R.C.P., I. O. K. Khaw, M.B., Ch.B., J. C. Noronha, M.B., B.S., E. O'Connor, B.M., B.Ch., A. B. Pestonji, F.R.C.S., L.R.C.P., E. A. Smith, L.R.C.P. and S., S. D. Stewart, M.B., Ch.B., E. E. Wilbe, L.S.A., H. F. Wilson, M.B., B.S.

University of Edinburgh.

The following received the degree of M.D. on December 17th:—*N. H. Bolton, **C. J. G. Bourhill, *G. Ll. Brunton, *G. C. Burgess, A. C. Court, *G. F. Fismer, J. Hewat, *J. P. Litt, *W. Macdonald, **N. D. Mackay, J. S. Manson, E. A. Milner, A. E. Moore, *T. P. Noble, *A. Z. Philips, J. Robinson, W. S. Thomson, *H. B. Watson.

The Leckie Mactier Fellowship of about £80 for three years has been awarded to W. Q. Wood, M.B., Ch.B.

** Highly commended for Thesis.

* Commended for Thesis.

Royal College of Surgeons of Edinburgh.

At a meeting of the College held recently, the following gentlemen, having passed the requisite examinations on 9th October, 1913, were admitted Fellows:—

John Bright Banister, M.D.Camb., M.R.C.P.Lond., Edmund Ewart Brown, M.B., Ch.B.New Zeal., Norman Huthnance Bye, M.R.C.S.Eng., L.R.C.P.Lond., Hugh Palliser Costobadie, M.R.C.S.Eng., L.R.C.P.Lond., Francis James Coutts, M.D.Lond., M.R.C.S.Eng., L.R.C.P.Lond., Arthur Dickson, M.D.Edin., etc., Charles Coyne Elliott, M.D. Western Univ., Canada, John Charles Boileau Grant, M.B., Ch.B.Edin., Norman Walter Mackworth, M.B., Ch.B.Aberd., Indian Med. Service, Carl Theodorus Moller, L.R.C.S.E., (Triple Qual.), M.B., Ch.B.Edin., Spencer Mort, M.B., Ch.B.Glas., Frederick Charles Pridham, M.R.C.S.Eng., L.R.C.P.Lond., Adolphe Henry Seelenmeyer, M.B., Ch.B.Melbourne, Reginald Eccles Smith, M.B., Ch.B. Leeds., John tennant, M.B., C.M.Edin., and Hermann Watson Webb, M.B., Ch.B.Edin.

Royal College of Surgeons in Ireland.

The folowing candidates have passed the First Dental Examination, Winter, 1913:—Peter E. F. Dunn, Patrick S. McCabe, Frederick Arthur McKinney, Thomas G. O'Connor, Stephen L. Wilson.

Final Dental Examination.—Gerald J. M. Dobbin, Robert L. O'Grady.

Primary Fellowship Examination.—Hugh M. Alexander, Norman McC. Boyce, Joseph V. Cope, King Elmes, Arnold K. Henry, Charles A. R. McCay, Balwant Rai, Hassan Suhrawardy.

Final Fellowship Examination.—Hubert C. Carden, Gianchand T. Hingorani, Oriel J. O. O'Hanlon, William C. P. Smyly, Philip J. Timony, Kathleen Wall.

Conjoint Examinations in Ireland.

The following candidates have passed the winter examination of the Royal Colege of Physicians and the Royal College of Surgeons:—

Preliminary Examination.—J. J. Brennan (passed with honours), Mary C. Albuquerque, John T. Alcock, Edward S. Becker, Vincent A. Carroll, Stephen Conway, Thomas H. Cooper, Robert J. Cussen, James Danaher, Benjamin Epstein, John A. Flynn, Stopford J. Halpin, J. A. Hamilton, William R. Henry, Norman L. C. Irwin, Patrick McAndrew, P. J. McGing, Charles McGlade, Edward J. Magner, Martin R. Morris, C. J. H. Mouritz, George O. Nightingale, Hugh O'Neill, James C. Rowan, V. A. Stack, Paul G. L. W. Suys, James F. Thornton, Richard Walters, F. J. Walsh, Robert P. Williams.

First Professional Examination.—Joseph Cusack, Louis Finnegan, Patrick J. Flood, William F. Moorhead, William H. Pierce, William H. Sexton.

Second Professional Examination.—D. Boland, Douglas L. Crowe, E. M. T. Crymble, T. Curran, R. D'Alton, Miss E. M. Lloyd-Dodd, E. C. H. Ewart, D. C. Kelleher, D. Lane Kelly, J. R. Little, E. T. McElligott, M. F. Murphy, P. O'Connell, Israel I. Sharpe, G. C. L. Woodroffe, J. Young.

Third Professional Examination.—R. M. Alcorn, S. Brown, S. J. M. Cairns, W. J. Dunlop, J. C. Fergusson, C. E. H. Gater, J. J. Gray, D. Kelly, J. Magner, W. G. D. McCall, F. R. H. Mollan, P. J. Murphy, J. A. Musgrave, J. O'Brien, P. J. D. O'Malley, Miss M. F. R. Welply, H. J. Villiers.

Final Professional Examination.—Richard J. Aherne, William K. Carew, James Crowley, James P. Fitzpatrick, John J. Keyms, Patrick Loy, Bruce Malaher, Samuel D. G. McEntire, D. Murphy, James V. Ryan, Patrick Rowan, James Sandys, Cecil R. Wallace, Robert A. Wright.

Diploma in Public Health Examination.—Henry H. Scott, M.D.Lond., with honours; George E. Beggs, L.R.C.P. and S.I., Jennette C. Hargrave, L.R.C.P. and S.I., Charles C. Iles, M.B.Edin.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

M.R.C.S., L.R.C.P. (South Shields).—The abnormally mild weather appears so far as one can judge by the weekly official statistics not to have interfered with the public health, which is somewhat surprising. In fact, the mortality is, if anything, somewhat under the average for the time of year, both in the metropolis and in most of the provincial large towns. Even in Dublin, where there is much unusual suffering in consequence of the prolonged strike, the death rate has not gone up.

WHEN CHRISTMAS DAY BE ON A THURSDAY.

As Christmas Day this year falls on a Thursday, it may be interesting to refer to an old poem which we found the other day among the Harleian MS. in the British Museum. It begins thus:—

> "If Christmas Day on Thursday be,
> A windy winter you shall see;
> Windy weather in each week,
> And hard tempests, strong and thick;
> The summer shall be good and dry,
> Corn and tracts shall multiply.

Well, we must "wait and see."

The Sunday at Home for December.

M.B (London, S.W.).—The classical "blue line" upon the gums is not infrequently absent in cases of lead poisoning, especially in persons who pay careful attention to dental hygiene. It is best seen when there is marked recession of the gums.

R. S. L. (Hampton Wick).—The subject is too technical to interest the majority of our readers. It would be better to offer the paper to a trade journal.

THE LEAGUE OF MERCY.

It was stated at the 14th annual meeting of this League held last week that the approximate totals for the year amounted to £17,227. This is a falling off as compared with last year, but last year there was a large contribution sent anonymously in response to the request for an extra £1,000 to make the contributions of the League to the hospitals up to £200,000. The League has now contributed to King Edward's Hospital Fund £201,034, making, with the £14,383 given to extra-metropolitan hospitals a total of £215,417 raised in 14 years.

F.R.C.S.Edin. (Crewkerne).—We are informed that the most up-to-date work dealing with medical mission work is *The Appeal of Medical Missions*, by R. Fletcher Moorshead, M.D., F.R.C.S. Sir Andrew Fraser, whose foreign experience gives him a claim to be heard, writes a cordial introduction. Messrs. Oliphant, Anderson and Ferrier are the publishers.

Appointments.

Gordon, J. L., M.D., Ch.B.Aberd., Acting Medical Superintendent at the Fountain Temporary Asylum.

Pratt, J. J., Colonel I.M.S., Surgeon to the Seamen's Hospital.

Rotherham, Arthur, M.B., B.C.Cantab., a Commissioner under the Mental Deficiency Act, 1913.

Sherlock, E. B., M.D., B.Sc.,Lond., D.P.H., Medical Superintendent of Darenth Industrial Colony.

Vacancies.

Hull and Sculcoates Dispensary.—Resident Surgeon. Salary £220 per annum with extras. Applications to J. E. H. Stickney, Hon Secretary. (See advert.)

Down District Lunatic Asylum.—Junior Male Assistant Medical Officer. Salary £170, rising to £200 per annum, with full extras valued at £100 a year. Applications to Resident Medical Superintendent. (See advert.)

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Denbigh (Denbigh), Glastonbury (Somersetshire), Pontyberem (Carmarthenshire), Slievereagh (Co. Cork), Teddington (Middlesex).

East Sussex Hosital, Hastings.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing. Applications to the Secretary.

Nottingham General Dispensary.—Resident Surgeon. Salary £220 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

County Asylum, Whittingham, Preston.—Assistant Medical Officer. Salary £250 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing. Applications to Medical Superintendent, Asylum, Maidstone.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, fuel, lighting, washing, and attendance. Applications to the Medical Superintendent.

Royal Surrey County Hospital, Guildford.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to the Hon. Secretary.

Royal Isle of Wight County Hospital, Ryde.—Resident House Surgeon. Salary £125 per annum. Applications to the Secretary.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Laboratories of Pathology and Public Health.—Fifth Assistant Pathologist. Salary £170 per annum. Applications to the Secretary, Laboratories of Pathology and Public Health, 38, New Cavendish Street, W.

Births.

Barnes.—On December 15th, at Eye, Suffolk, the wife of Henry E. Barnes, M.D.Lond., of a daughter.

Beck.—On December 21st, at Bromyard, the wife of Ashton Beck, M.B., of a daughter.

Cunningham.—On December 13th, at Boksburg, North Transvaal, the wife of Norman Rowsell Cunningham, M.R.C.S., L.R.C.P., B.A.Cantab., of a son.

Fernie.—On December 13th, at 24, Crooms Hill, Greenwich, the wife of C. H. Fernie, M.R.C.S., L.R.C.P., of a son.

Gunn.—On December 18th, at Neston, Cheshire, the wife of George Gunn, M.D., F.R.C.S.E., of a son.

Jobson.—On December 19th, at Trelyon, Ilford, the wife of Dr. T. B. Jobson, of a son.

May.—On December 19th, at Woodleigh, Ware, Herts., the wife of George E. May, M.R.C.S. and L.R.C.P., of a son.

Marriages.

Cruise—Woolcombe-Boyce.—On December 13th, at St. George's, Hanover Square, W., Richard R. Cruise, F.R.C.S., of 85 Harley Street, W., only child of the late Francis Cruise, of Rahood, Co. Meath, to Margery Barbara, only child of the late Hugh Woollcombe-Boyce, Capt. 6th (Carabiniers) Dragoon Guards.

Garnett—Crawford.—On December 18th, at the Cathedral, Glasgow, Graham Hogg Garnett, M.D., of Greenwich, elder son of the late Harry Garnett and Mrs. Garnett, of Georgetown, Demerara, to Susan, youngest daughter of the late James Crawford, of Shawton, Glassford, and Mrs. Crawford, of Stonelaw Tower, Rutherglen, N.B.

Hayman—Atwood.—On December 18th, at St. Barnabas Church, Tunbridge Wells, Charles Augustine Hayman, J.P., M.D., F.R.C.S., of Kingston Villa, Richmond Hill, Clifton, Bristol, to Elizabeth Caroline, daughter of the late Captain Atwood and Mrs. Atwood, of Brixton.

Langdon—Smith.—On December 20th, at St. Stephen's, Ealing, William Morgan Langdon, M.R.C.S., L.R.C.P., of Hillside, North Tawton, Devon, second son of Captain C. H. C. Langdon, R.N., of Winchester House, Bedford Hill, Balham, to Rosalind Aline, only daughter of Commander C. V. Smith, R.N., of 25 Ravensbourne Gardens, Ealing, and the Hydrographic Department, Admiralty.

Deaths.

Fagge.—On December 20th, at Hythe House, Lutterworth, Alice, the wife of Herbert W. Fagge, M.R.C.S., L.S.A.

Harris.—On December 15th, at Mildenhall, Suffolk, Frederick Hills Harris, M.R.C.S., L.S.A., in his 91st year.

Mole.—On December 18th, at Swansea Hospital, Alfred Ernest Mole, M.B., C.M.Edin., late of Reynoldstone, Glam., in his 45th year.

Rutter.—On December 16th, at 11 Wilbury Gardens, Hove, Joseph Rutter, M.D., in his 80th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, DECEMBER 31, 1913. No. 27.

NOTES AND COMMENTS.

An Awkward Dispute.

IN such a many-sided science as medicine there is always plenty of opportunity for differences of opinion among its professors upon any point that is at all debatable. The public are not a little amused when swords are crossed by medical men over some professional matter regarding which many different opinions may be held quite legitimately. During the past few weeks a somewhat protracted controversy has been raging at Cheltenham owing to the differences that have arisen between Dr. J. H. Garrett, the Medical Officer of the Borough, and Dr. Alice Burn, the assistant and School Medical Officer, in the matter of food reform. It is reported that the former believes in the value of an ordinary mixed diet, while the latter not only advocates the adoption of vegetarianism, but has given lectures in her own time advancing her views. Dr. Garrett, holding that, as Medical Officer, he was responsible for the medical policy of the borough, objected to the lectures being continued after he had announced that they were contrary to his policy, and he declared that either he or his assistant should resign. Dr. Alice Burn held to her point, and Dr. Garrett therefore tendered his resignation. At this stage the Board of Education stepped in, and Sir George Newman, having heard both sides of the case, decided that Dr. Burn should either apologise to Dr. Garrett or resign her position. Dr. Burn has chosen the latter alternative, whereupon the Cheltenham Education Committee agreed to allow Dr. Garrett to withdraw his resignation. Apart from the question of the comparative values of a flesh or a fruit diet, it may be held that it is unwise for any subordinate officer to advance in public opinions directly opposed to those of the head of the department. A house-surgeon who treats an in-patient in an exactly opposite manner to that ordered by his chief, unless he knows that such treatment would be directly harmful, is wanting in loyalty, and, similarly, an assistant medical officer of health who does not carry out the wishes of his principal can hardly be said to act with that *esprit de corps* which should characterise the work of an important department of municipal life.

Is Debility a Disease?

EVERY medical man knows that there are many cases in which disability to work results, not from any real morbid entity, but from a state of general weakness. The strictest medical examination will often fail to reveal any very marked departure from the normal, but, nevertheless, the patient insists that he is quite unable to follow his ordinary occupation. The word "debility" is frequently used upon medical certificates for exemption from work, though it cannot be said that the term is strictly scientific, nor does it claim to be a diagnosis. A case was tried the other day at the Leicester County Court, before his Honour Deputy-Judge Woodgate, in which a married woman claimed an injunction from the Insurance Section of the Co-operative Wholesale Society, Limited, to restrain them from refusing to accept for her as evidence of her claim to sickness benefit under the National Insurance Act a medical certificate stating that she was suffering from debility, because no specific disease was mentioned. Medical evidence was brought forward to show that debility was a sufficient cause for disablement, and, therefore, a suitable word to appear upon a medical certificate. A verdict was given for the plaintiff on the ground that the society was bound by the text of its own rules, and there appeared to be nothing in these against the acceptance of the wording of the certificate. It may be urged that debility lasting for more than a few weeks may be merely a symptom of some graver affection, such as anæmia, early phthisis, or Addison's disease. In the interests of science, it is most desirable that ambiguous terms should be avoided, and in order to prevent legal disputes it is better to employ a more precise description for the cause of incapacity for work upon medical certificates.

Biplane "Looping."

IT is not sufficient merely to fly nowadays, for aerial locomotion almost ceases to create excitement among the spectators. To be really up to date the would-be airman must be prepared to cause a temporary sensation by flying upside down. This inversion of the aerial order of things cannot be without some influence upon the animal economy of the flier. The world was startled the other day by the daring feats of Pégoud and Hucks in "looping" with a monoplane, and now Chanteloup, the French airman, has succeeded in going through a similar performance with a 60-h.p. Caudron biplane in half a gale. A medical man has contributed to the *Times* a few interesting notes regarding the physical condition of M. Chanteloup at the conclusion of his remarkable flight at the Hendon Aerodrome last week. Contrary to expectation, his pulse-rate was found to be only 88, and the pulse quiet and steady. It was also regular, and free from the least suspicion of a tremor or jerkiness. There were none of the characteristic twitchings of the tendons at the wrist so often seen as the result of some unusual muscular effort. The airman's eyes are said to show a "very wide range of lateral oscillation, due, no doubt, to exceptional development of the ocular muscles." A high degree of nervous control and self-possession is essential for all who aspire to conquer the art of flight, and with this M. Chanteloup certainly seems to be well endowed. Considering the exceptional demands made upon the circulatory and nervous systems in navigating the air, it seems almost a truism to assert that none should attempt to fly who are the least degree abnormal in these respects.

Infection in Books. A mild sensation is periodically caused by the announcement in the lay press that infectious diseases are transmitted by the lending department of free libraries. Anyone familiar with the odour of returned volumes of popular fiction can hardly help comparing it with that of a living-room in which the window is never open. Sometimes it is stale tobacco, or else it is a washed-out perfume that gives the characteristic odour to the well-worn yellow-back, whose pages bear occasional trace of having been the companion of some solitary individual at mealtimes. Of the germ-contents of such books little has been said, but there can be no doubt that both covers and pages harbour a large number of micro-organisms, pathogenic and otherwise. According to the librarian of the Kaiser Wilhelm Academy in Berlin, tuberculosis is the disease most likely to be spread by books, and after this come diphtheria, scarlet fever, and small-pox. It is said that inoculation experiments with guinea-pigs have given positive results, these animals having died of tuberculosis and septicæmia after injection with aqueous extracts of old books. Happily the modern municipal free library, with its clean and orderly counters and shelves, is so well managed that little need be feared on the score of infection, for the rules are most stringent in connection with books lent to readers in cases where any infectious disease exists. It should be quite possible to provide a clean, renewable cover every time a book is given out to a fresh reader. In scientific and medical libraries, of course, the risk is practically non-existent. A special providence seems to be attached to bibliophiles, for it has not been proved that the vendors of secondhand books suffer in health more than those who deal in new volumes only.

Coroner and Medical Evidence. From the North of Ireland comes an extraordinary story of the conduct of a coroner in regard to the summoning of a medical witness. The jury, having heard the evidence submitted to them, demanded that the medical man who had attended the deceased should be called. The coroner, saying that it was not a matter for the jury which witnesses should be called, refused their request, and on their expressing their inability to bring in a verdict, kept them locked up for four hours. The jury remaining obdurate, the coroner then examined another medical man whom he had ordered to examine the body. The practitioner who had attended the deceased was not examined, though he was present in court. We fail entirely to understand the position of the coroner. The point appears to be covered by Sec. 34 of 9 and 10 Vic., cap. 37: "And be it enacted, that whenever it shall appear to the majority of the jurors upon any inquest that the cause of death has not been satisfactorily explained by the evidence of such medical practitioner, or of the witness or witnesses who shall have been examined at such inquest, it shall be lawful for the said jurors, by a requisition in writing, to call upon the coroner to issue his summons for the attendance of some other legally qualified medical practitioner or practitioners; and if the coroner, on the receipt of such requisition, shall refuse or neglect to issue his summons as aforesaid, he shall be deemed guilty of a misdemeanour." The matter is one which should be taken up by the Irish Medical Association.

LEADING ARTICLES.

THE PRINCIPAL MEDICAL EVENTS OF THE YEAR 1913.

It is not an easy matter adequately to summarise within a small compass the most important medical features of the year which expires to-day. One event, however, stands out prominently from among the rest, namely, the great International Medical Congress which met in London in August under the presidency of Sir Thomas Barlow. The work of the twenty-six sections of this huge conference was duly reported in our columns at the time, and it was the general opinion that the gathering was an unprecedented success. The increased attention paid by the medical profession to the prevention and cure of syphilis, aided by the powerful stimulus provided by the resolutions passed at the Congress, led to the formation of a Royal Commission on Venereal Diseases, under the chairmanship of Lord Sydenham, which has already held several sittings. Shortly after the institution of this inquiry, a valuable report upon venereal diseases, by Dr. R. W. Johnstone, was issued by the Local Government Board. Further progress in syphilology during the year may be measured by the discovery by Noguchi of the treponema pallidum in the central nervous system in cases of general paralysis, and by the demonstration by McDonagh of the life-cycle of the same organism, and the working-out by the same observer of its bio-chemistry. Considerable activity has been shown in connection with tuberculosis, notably in the more general institution of tuberculosis medical officers by local authorities, and the better local administration in England with regard to sanatorium benefit under the National Insurance Act. The final report of the Departmental Committee on Tuberculosis was issued in March, and in February the Order with respect to the compulsory notification by all practitioners of all forms of tuberculosis came into effect. Much interest was aroused by the discovery of several cases of pellagra indigenous to this country. The resemblance of this disease to certain skin and mental disorders has been reported upon by various observers, notably by Sambon and Box, and the former has expressed his view that pellagra is connected with the simulium fly. The Mental Deficiency Act of 1913 marks an important stage in the growth of the responsibility of the community for a large class of its weakest and most backward members. The Colonial Office has shown that it is fully alive to the hygienic needs of many of our fellow-subjects by appointing a Committee to report upon the spread of disease in Africa by wild animals and tsetse flies, and also a small Commission to inquire into the nature and frequency of West African coast fevers. The British Medical Association held a successful annual meeting at Brighton, when the motion to form a trade union was defeated by a heavy poll of representatives. An important outcome of this decision has been the formation of the National Medical Guild, designed by its promoters to work in conjunction with the British Medical Association, and not in opposition thereto. One of the most important legal cases during the year was the vivisection libel suit, which resulted in a verdict for the defendants, consisting of the *Pall Mall Gazette* and Dr. Saleeby, after a trial lasting sixteen days. Among other interesting medical events may be mentioned the celebration of the Livingstone Centenary and the appointment of a medical man, Dr. Robt. Bridges, as Poet Laureate. Space will not permit us to enumerate the many important lectures delivered before the Royal Colleges of Physicians and Surgeons, neither are we able to record the detailed progress of every special department in medicine or surgery. It will be seen, however, that the *annus medicus,* 1913, has, in more ways than one, proved a worthy successor of its forerunners.

COMPULSORY OPERATIONS UNDER THE CHILDREN ACT.

A recent appeal case, to which a brief allusion was made in our last issue, is of considerable medico-legal interest, and bears materially upon the administration of the Children Act, 1908. In January last one Jackson was proceeded against under the above-mentioned Act for having unlawfully and wilfully neglected his child, Hilda Jackson, in a manner likely to cause unnecessary suffering or injury to health. The facts brought in support of that charge were: That the said child, on January 18th, 1913, was and had for some time previously been suffering from adenoids, which were causing mental dulness, impaired breathing, and deafness and some anæmia, and that consequently the child was suffering injury to her health which required to be remedied, and that the only possible remedy was a surgical operation for the removal of the adenoids. That the respondent on the said January 15th, 1913, had neglected and refused, and did then neglect and refuse, to allow the said child to undergo the operation necessary for the removal of the adenoids. That the said operation was not a dangerous one, but that in all probability it would necessitate the administration of an anæsthetic. That the respondent and his wife (the mother of the child) did not consider an operation necessary and did not believe in operation, and refused to allow the child to go to the infirmary to have the operation performed." It should be noted that, beyond the refusal to allow the said operation to be performed no evidence of neglect of the said child by the respondent was given. After considering the evidence submitted to them the justices came to the conclusion that the respondent was under no legal liability to allow the operation to be performed, and that the refusal to allow such operation to be performed did not constitute neglect to provide adequate medical aid within the meaning of the Act. The question for the Appeal Court was whether the justices, upon the statement of facts, came to a correct determination and decision in point of law. The three judges in the higher court —Mr. Justice Darling, Mr. Justice Avory, and Mr. Justice Atkin—agreed in the view that the magistrates should have convicted, and the case was accordingly sent back for re-hearing. In delivering judgment, Mr. Justice Darling said the justices must decide each particular case as it arose, and it was no answer in law that the parents did not think an operation necessary or did not believe in operations at all; though the refusal to allow an operation was not necessarily such a refusal to provide medical aid as to amount to wilful neglect within the section. The justices must, in deciding whether there had been wilful neglect, consider in each case what was the nature of the operation, and the reasonableness of the refusal to have it performed. In concurring with that view, Mr. Justice Avory added the important observation that in each case the justices must consider who the person was who had required the operation to be performed—whether it was ordered by a qualified medical man, or whether it was merely a suggestion of some irresponsible person. That remark has a vital bearing upon the ultimate practical value of the Children Act. Upon the introduction of the measure we pointed out how potent a weapon it placed in the hands of magistrates and coroners for the suppression of quacks and quackery. Mr. Justice Avory's view in this case may be commended to Mr. Lloyd George's Insurance Committees, who are recognising certificates granted by herbalists and other medically unqualified persons. So far as adenoid operations are concerned, the case has established the important principle that the refusal of parents to permit operation is unlawful, but to that general proposition there are certain modifying conditions

---

CURRENT TOPICS.

British Medical Association.

An extraordinary general meeting of members of the British Medical Association was called at 2 p.m. on Tuesday, December 23rd, at the Strand offices of the Association. As the necessary quorum of one hundred members was not present, the meeting was adjourned until Tuesday, the 30th, at the same hour. It should be explained that, by the rules of the Association, no quorum is fixed for an adjourned meeting of the kind, so that were only one member present he would be able to conduct the whole business. As the business before the meeting is presumably to settle the question of raising the subscription to £2 2s., and of the proposed extension of borrowing powers, it is evident that the decisions arrived at are of vital importance to the Association. It is much to be regretted that the press of urgent business has delayed matters of such weight and urgency to the last few days of the year. It is clear that few provincial members would be able to journey to London a couple of days before Christmas. In London, again, some members would be out of town, while others, whether consultants or private practitioners, would find it impossible to attend a meeting at 2 p.m. in the holiday time. We can have nothing but commiseration for a Council that has been forced to submit decisions of supreme moment to a meeting summoned in the face of so many difficulties. It is obvious, moreover, that any member disapproving the decision of the extraordinary general meeting desiring to send in his resignation, would have but one day of the year left in which to give notice of his withdrawal. In other words, the majority of members are bound by the decision of December 30th, 1913. It is a matter of some surprise that the attention of members has not been called to the failure of the extraordinary meeting of the 23rd in the issue of the 27th, and that the objects of the meeting and its full significance were not dealt with editorially—that is to say, apart from a brief formal announcement in the Supplement, without a word as to the nature of the business to be discussed. Possibly we have been misinformed as regards the agenda, but in any case the information vouchsafed by the executive cannot be regarded as adequate and satisfactory.

Unnecessary Anatomy.

Medical education is a vexatious subject. Its discussion is daily and its solutions several and sempiternal. Professor Harvey Cushing thinks we have too much of the rudiments. It is true that the student spends an enormous amount of time at anatomy. In the lecture-theatre, at demonstrations and dissections he learns, or has opportunities of learning, much more than will ever be of use to him. Details of human structure are forced into the student on the slightest provocation. The essence of education is selective forgetfulness, and the thing most men start forgetting with the greatest rapidity and ease is such facts as the function of the dentate fascia and the exact origin of the components of the erector spinæ. And it is a good thing that they do. Except in a few specialties, the medical man has no use for such infinitesimal information. The general practitioner—and, after all, he is the average and the important medical man—needs breadth of knowledge primarily, not depth. He wants to know when a case is beyond him. The specialist cannot know too much of his subject, and, with his comparatively narrow objective, we have a right to expect a good deal of detail from him. But it is as absurd to teach the everyday doctor all the fine points a monomaniac professor wishes him to know, as it is to make a dentist qualify in reducing a dislocated hip. To-day, of course, we do both. We all had to learn a great deal of what was quite unnecessary. But it is sheer spite to condemn posterity, even if it has done nothing for us, to share our toils without the need.

The Plumber of the Future.

The ordinary citizen, cumbered with the multifarious business of life, is apt to take many things on trust, and to bestow little thought on the hidden agencies that preserve the comfort and safety of his life. How many of us, for instance, think of the debt of gratitude we owe to the plumber, whose handiwork is absolutely necessary to the sanitary safety, comfort and convenience of the modern household! Think what must happen were the plumbing of the water supply, or the drains, or the hot-water pipes, or the gas or electric lighting systems to go seriously wrong! The inmates of a house suffering from such a break-down would be exposed to the risks of sewage and of water-borne disease, not to mention drought, darkness, coal-gas poisoning, fires and explosions. To put the matter in a nutshell, good plumbing is a first essential of good housing. As things go, however, there is no guarantee that a plumber has done his work properly. To remedy this state of affairs has long been the desire of the Plumbers' Company, a body founded by Royal Charter in the time of King Edward III.—1325 to 1375. At that time it was customary for each plumber to distinguish his own handiwork by a private mark of his own. That practice the Plumbers' Company wish to revive, and it has also spent large sums of money in promoting legislation with a view of securing the proper training and registration of plumbers. There is a good deal to be said in favour of this policy, some idea of which can be gained by reading the report of the speeches at the recent Plumbers' Livery Dinner, which will be found elsewhere in our columns; indeed, a similar principle might be extended with advantage to various industries other than that of plumbing.

The Season's Eatings.

There is often a lull in the doctor's daily work about Christmas-time, but it is the lowering calm that goes before the storm. Christmas celebration does not often indicate cerebration in the celebrants. Why a festival primarily religious should be made the occasion for over-working the œsophagus, stretching the stomach, and generally abusing the alimentary tract is one of the hidden mysteries, the frequency of whose occurrence alone has numbed our power of astonishment. A recurrent miracle becomes a platitude. Some medical men have lately amused themselves by extolling the dietetic perfection of the plum pudding, mince pies and other complements of the season. In an altruistic profession such as ours we suspect nothing but a cheap craze for originality, the *technique* of which consists in taking the accepted view of anything, inverting it and trying to bolster up the inversion. For all that we prefer, and experience is on our side, the old-fashioned idea. For a few days *laissez faire* is our motto—with the "fair." We know it is bad for us, but we do not mind. We may be fools, but we are brave enough to rejoice in our folly; we have the courage of our convictions; if we over-eat ourselves the game is worth the scandal. As human beings let us enjoy ourselves a little while to-day—to-morrow we shall learn that the relations between Christmas and chrismol are more than phonetic. As medical men we may hold that the conventional festivities do no one any real harm, and if we have to contend with a superabundance of minor ills just now, we can always console ourselves with the cheery thought that where there's a pill there's a pay.

Mortality among Negroes.

Even in our own country people are sometimes quite ignorant of their precise age. The negroes of tropical Africa appear to be universally so, since there is no official registration of birth. It is difficult, therefore, to frame accurate mortality statistics in the absence of any definite knowledge as to age. In a recent issue of the *Archiv für Schiffs und Tropen-Hygiene*, Dr. R. Mouchet, of Liège, who has been working for two years at Leopoldville, in the Middle Congo, where he has performed more than one hundred *post-mortem* examinations of natives, asserts that the native dies far younger than the European. His reasons are interesting. In the first place, a grey-haired native is rare, nor is obesity often seen. Cataract, tumours, atheroma, and kidney disease are hardly ever found, and ossification of the costal cartilages is exceptional. Further, a native generally dies from a single uncomplicated disease, and when his body is examined *post mortem* there are frequently no associated lesions found accompanying the effective cause of death; they have not had time to develop. The negro has a lesser vital resistance than the European, and this whether for a disease new to him, as tuberculosis, or for tropical diseases against which his race has struggled for generations. Dr. Mouchet ascribes this feeble resistance to poor food, bad housing, and intestinal parasites. In 127 bodies examined, ankylostoma occurred in 114; only seven were quite free from intestinal parasites. Then, too, the native dies very often from amœbic dysentery, or from the perforations it causes, rarely living till a liver abscess has time to form; while the European survives the first onset of the disease, and if he succumbs later it is due to the abscess. Tuberculosis is the chief cause of death, and gave occasion for 37 in 100 necropsies. Smallpox has almost disappeared, thanks to vaccination; and in the same district trypanosomiasis has been overcome, for there are now no longer any *glossinæ*.

Actinomycosis in Imported Ox-Tongues.

An interesting report has recently been issued by the Medical Officers of Health for the City and Port of London, Dr. W. J. Howarth and Dr. Herbert Williams, upon the result of a careful examination of a large number of tongues imported from Argentina. Information had been received on July 31st last from the Local Government Board that tuberculous and actinomycotic lesions had been observed among certain tongues, and as a consequence 85,445 tongues were examined. Of these, 4,949, or 5.8 per cent., were rejected an account of showing lesions which were practically all those of actinomycosis. The disease was identified by smears and sections, and was found to affect the blade of the tongues or to be localised in the glands, the latter situation predominating. Every tongue required to be defrosted before examination, so that the difficulties of the investigation were not inconsiderable. The frequency of the lesion in the glands indicates the necessity for importers ensuring that the glands are left attached to the tongue, and not removed, as was the case in a percentage of tongues examined in certain consignments. The report concludes that, until action is taken in the Argentine which will ensure that these tongues are carefuly examined, and all those presenting lesions are withdrawn, it will be necessary for the sanitary staff to continue the present arrangement of examining every tongue received at the Port and City of London. It is recommended that regulations should be framed rendering the importation of tongues without the root and glands attached liable to re-exportation. Drs. Howarth and Williams and their staff may be congratulated upon the promptness and energy they have shown in bringing to the notice of the authorities a matter affecting so strongly the vital interests of the public, and it is to be hoped that their recommendations may be acted upon with as little delay as possible.

PERSONAL.

Miss Eleanor Davies-Colley, F.R.C.S.Eng., has been reappointed Surgical Registrar to the Royal Free Hospital.

Fleet-Surgeon C. I. Mansfield, M.V.O., has been promoted to the rank of Deputy Surgeon-General in His Majesty's Fleet.

Dr. E. Colston Williams has been appointed Medical Officer of Health and School Medical Officer for the County of Brecon.

Dr. Sidney John Cole, M.A., M.D., B.Ch.Oxon., has been appointed Medical Superintendent of the Wiltshire County Asylum.

Professor Dr. Ernest Ehlers, of Göttingen, has been elected a corresponding member of the Zoological Society of London.

Dr. J. Le Fleming C. Burrow, M.B., Ch.B.Edin., M.R.C.P.Lond., has been appointed Honorary Physician to the Leeds Public Dispensary.

Dr. William Carnegie Brown, M.D., C.M., joint secretary of the Society of Tropical Medicine and Hygiene, left estate of the gross value of £49,886, of which £44,225 is net personalty.

Capt. R. Kelsall, Indian Medical Service, has obtained the Gold Medal of the University of London in Branch 6 (Tropical Medicine) for the M.D., at the London School of Tropical Medicine.

Dr. Andrew Love, Physician Superintendent of the Greenock and District Combination Hospital at Gateside, Greenock, has been appointed Tuberculosis Officer and Medical Superintendent of the Lanarkshire Burghs Sanatorium.

Dr. Leonard Guthrie will deliver his presidential address before the Harveian Society of London, on "The Early Transactions of the Harveian Society," on January 8th, 1914, at the Stafford Rooms, Tichborne Street, Edgware Road, W.

We regret to learn that Dr. Thomas W. Mason, of Tooting, met with a serious accident on Sunday night, when his motor car collided with another, with the result that of two friends riding with him one was killed and the other seriously injured. Dr. Mason himself is suffering from concussion and shock.

The Rev. S. Scobell Lessey, M.D., Chaplain Superintendent of Abbotswood House. Temple Memorial Home for Male Inebriates, will open a discussion on the Male Inebriate at a meeting of the Society for the Study of Inebriety, to be held on January 13th, 1914, at 4 p.m., at 11 Chandos Street, Cavendish Square, W.

Dr. William Bower, who has recently retired from Hendon on the ground of ill-health, was the recipient the other day of a handsome testimonial, which took the form of a beautiful grandfather clock in a mahogany case with two sets of chimes, from his grateful patients in token of their appreciation of his services rendered during his eighteen years' residence in the district.

CLINICAL LECTURE

ON

PYREXIA—COUGHS—IN CHILDREN.

By SHEFFIELD NEAVE, B.A.Oxon., M.R.C.P.Lond.,

Late Physician to the Queen's Hospital for Children, London.

PYREXIA.

THE ætiology of Pyrexia when unaccompanied by other signs is often difficult to elucidate, though its proximate cause is of course some disturbance acting on the heat centre.

The nervous system of children as opposed to adults is easily provoked to pathological action and it is from this cause, too, that we find a greater irregularity in them of such functions as the pulse, the respiration and the action of the sphincters, so that we can hardly expect the thermic system to escape, and as a fact, on the contrary, it is very easily disturbed. It can be shown that after birth the nervous system of a normal human being has gradually to acquire the stability and the co-ordination of maturity during the first twelve years of life or so.

The nervous system also in children is very variable in its behaviour in different cases, and what one may expect in this way in one family is quite different from that in another; in fact, children are by no means always made in the same mould and have many idiosyncrasies in their development.

On one occasion I found two children of the same family constantly having rises of temperature which were never accounted for, and this extending over a period of some years. Another in the same family had a similar history. Again in the wards of a children's hospital it is quite common to be unable to account for a rise of temperature perhaps extending over several days so that it has even been thought that any general excitement such as a violent fit of crying or of a joyous character may be sufficient cause in a case where the system lacks normal resistance at the moment.

When one is called to a case of pyrexia without further symptoms one should be prepared with some habitual line of thought in order to do justice to the case.

The general maxim that one should always take enough time to thoroughly examine every case if one does not mean to be caught napping is very important here. Such a thing is obviously not always possible in all kinds of practice, but the neglect of it is the cause of most errors made, so much so that a great deal of the work of a consulting physician consists in pointing out things quite easy to discover if a complete examination had been made.

One of the first things is to search for a collection of pus in any part of the body, but we are here dealing with things medical as opposed to things surgical so we will leave this and run through the more common ailments in which a somewhat prolonged pyrexia may be the only sign at the commencement. Omitting the specific fevers of childhood such as measles and scarlet fever, we will consider the following more common diseases which may bring about pyrexia without an obvious cause at the onset.

(1) Acute tuberculosis.
(2) Rheumatic fever.
(3) Enteric fever.
(4) Constipation.
(5) Bacilluria.
(6) A less common group, viz., Middle ear disease, Hodgkin's disease, Leucæmia, Syphilis.

(1) In children, acute tuberculosis usually is an exacerbation of a more chronic state of which there are probably some signs, but there are cases where it becomes generalised from some internal focus that cannot be diagnosed. While this is going on it is more of a blood infection than is usual in adults, especially in smaller children, and this state may well account for such a temperature without other signs. Again an internal focus, without being actually in the process of dissemination, may of course account for a raised temperature.

The nature of the *pyrexia* such as its remission in the daytime and exacerbation in the evening, together with night sweats if present, will assist us, and if later tubercle of the choroid can be seen the diagnosis is complete. Von Pirquet's reaction may be of some value for the purpose of diagnosis, though not so much so in older children (an injection of old tuberculin would be more reliable, but cannot be well used while the temperature is raised), thus it may be some time before the practitioner is in a position to make up his mind as to diagnosis.

It is not of uncommon occurrence, as we have seen when discussing wasting, to find at a *post-mortem* examination the lungs, spleen and other organs studded with miliary tubercle, none of which are open, and which, in the absence of signs, have never been diagnosed in life. It is easy to see that such a state of things may often produce pyrexia without other symptoms or signs in its first stages.

(2) Rheumatic fever may also be the origin of the difficulty, for in a child of that diathesis an aborting attack may give but little or no other sign. Consequently it is of importance to ascertain the personal and family history in the respect of this complaint, and to note any tendency to inflammation of the throat structures, and the tonsils in particular, any question of joint or limb pains, as well as hyperhydrosis. An exhaustive examination of the heart is of course indispensable, as this is the most vulnerable point here in children. All this should be done for the purpose of finding some confirmatory fact. On this head, too, it is as well to mention the necessity of diagnosing osteomyelitis from rheumatic fever, but the pain is usually sufficiently early in the disease to give the clue to which is the cause of the pyrexia.

(3) Enteric fever is very atypical in children, and is one of the most difficult things to exclude in these cases, as without regular signs and symptoms we have only Widal's test or a blood culture

to fall back upon; the former is only available after the seventh day, and the latter may not be positive, at any rate on the first experiment, so that in both cases much time may elapse. A prolonged temperature not otherwise accounted for in other ways should always raise suspicion in one's mind as to this disease.

The following case will illustrate the difficulties that may arise. A case was diagnosed as tubercular hip disease and died suddenly. It was shown at the *post-mortem* examination that although there was pus in the hip joint, this contained the typhoid bacillus, and that the child had died of perforation of the bowel. Except the pain in the hip joint and the temperature there had been no other symptoms.

(4) Another cause of simple pyrexia is constipation, and unless it be excluded frequent mistakes will be made. This appears at first sight to be a simple matter, but there are pitfalls. Thus it has often been pointed out that a daily motion of the bowels may occur, notwithstanding there are retained fæces, and it is probable that while these remain in some of the folds of the bowel the fæces of daily production slip by. This state of things may easily lead to the mother stating that she has no difficulty with the child's bowels, and that he has a good motion daily. In a doubtful case of pyrexia, therefore, the abdomen should be carefully palpated for accumulations in the bowel, especially in the sigmoid flexure, and an enema or an aperient given. It is surprising how many of these cases clear up under this simple treatment. The grandiloquent names of " Intestinal stasis and intestinal toxæmia," probably include some of these cases, a good many of which at the hands of an eminent surgeon have undergone excision of the colon. Still mentions a case of recurring pyrexia which had been treated for influenza, pneumonia, peritonitis and typhoid, and appeared to get well quickest by administering small doses of calomel.

In connection with the above, helminthiasis should be thought of and excluded.

(5) *Bacilluria.*—Another solution of the riddle may not unfrequently be obtained by an examination of the urine for organisms. The commonest is probably Bac. coli com. which is said often to make its way into the urino-genitary system through the walls of the pelvis of the kidney from the intestine or blood, as well as by the external orifice of the urethra. When this is the case a simple pyrexia is often the only sign, and the child will perhaps seem but little out of sorts. It is not easy to get rid of the bacillus from the genito-urinary system, which might be well expected if it has actually invaded the kidney, but a vaccine often relieves the symptoms quite promptly.

(6) The onset of meningitis is often insidious, and pyrexia may be the first sign to arrive, especially when it is of the tubercular variety, seeing that tubercular meningitis is usually the result of the disease when generalised. Meningitis should therefore not be forgotten, and the various signs announcing its advent looked for, thus a desire to be left alone, photophobia, and the cephalic cry, or any of them, are matters of great importance. In the tubercular variety the temperature is seldom really high, rarely above 101, and in the basal meningitis even if high, it will usually at times remit completely.

There remain two or three affections which I think should not be left unmentioned, notwithstanding that they are less frequently a cause of prolonged simple pyrexia at the onset. I refer to middle ear disease, Hodgkin's disease, leucæmia and syphilis.

(1) Otitis media usually declares itself in other ways than by mere pyrexia, but there are cases where the pain is too slight to be discovered by those about the child, and where the disease is essentially chronic for the time, being only thus manifested. Hence a careful investigation of the ears is absolutely necessary for the exclusion of this, and even so the practitioner may be left in uncertainty.

(2) Hodgkin's disease usually commences by the enlargement of the glands on one side of the neck. As the causes of gland enlargement are so numerous it is often difficult to positively exclude it as a cause of pyrexia in its early commencement, however unlikely one may think it. The temperature is often intermittent, and the blood count at first at any rate is rarely affected.

(3) If leucæmia is suspected as the cause, a blood count here is much more likely to be of use, and enquiries should also be prosecuted as to enlarged glands, as well as enlarged abdomen and shortness of breath.

(4) Congenital syphilis, though usually manifested in other ways, may be more rarely a cause of simple pyrexia. If it is suspected the Wassermann test should be tried and if positive, the appropriate remedies will usually be successful in bringing the temperature to the normal.

COUGH.

Coughs in children are more diverse in their causation than in adults, as the state of their nervous system produces less stable co-ordination.

Diagnosis therefore at times is by no means easy in respect of ætiology.

A cough is produced by some reflex stimulus of the vagus, which incites the organism to make a sudden expiratory effort, as if in the act of trying to eject something from below the larynx, by bursting open the closed glottis. This effort is often successful when this something exists, as in the case of mucus in the bronchial tubes.

On the other hand there may be nothing to expectorate and the real source of irritation may be found elsewhere, *e.g.*, the area of the pharyngeal branch in the naso-pharynx and fauces, and it is thought by some that this cause is the more frequent in children. Other branches of the vagus, too, may also be responsible for this reflex stimulus.

It is proposed here to deal chiefly with this class of case, viz., coughs which are not due to a pathological state of the lung, at any rate in the first place.

In diagnosis as to whether a cough is due to lung affection or not, the rate of respiration will be of much assistance, as these local irritations are not likely to increase it.

Some useful generalisations can be made and a good deal gathered from the nature and characteristics of the sound produced and from its immediate effects such as vomiting.

We may therefore be permitted to divide coughs into those which are spasmodic and those that are not so, and the non-spasmodic into harsh, dry coughs and those that can be heard to be producing expectoration.

(*a*) Spasmodic.
(*b*) Non-spasmodic.
  I. Harsh and dry.
  II. Expectorative.

(*a*) The cough of pertussis is the definitely spasmodic, and it may be taken as a type of this class *par excellence*. Every one knows the characteristics of this cough; the sudden paroxysmal violence, the protruded tongue, the swelled face, and often the resulting vomit, and although all these may not always be present, yet to an ear that has heard it only a few times, the general effect is easily recognisable, so that this disease may often be discovered thereby even without a whoop.

At the same time there are other causes which produce something of the same result, of which the following are instances:—

(1) Bronchial glands enlarged.
(2) Long uvula and adenoids.
(3) Bronchiectasis.
(4) Fibrous lung.
(5) Foreign body.

(1) *Enlarged Bronchial and Mediastinal Glands* pressing on the trachea and bronchi are often responsible for spasmodic cough, and one has to be on one's guard in the matter. In fact, considering how often tubercle of the lung follows pertussis, how often the cough of pertussis persists for even months after the attack without the whoop (but with the other characteristics), and how often tubercle commences in the bronchial glands, it is quite possible that these glands are tuberculous and responsible owing to their pressure effects, and therefore such a persisting cough must be looked upon with grave suspicion.

(2) *Night Cough* is often due to adenoids or long uvula. Here the child may wake up in the middle of the night and undergo a violent choking fit of coughing, often accompanied by a night terror, the two together causing much alarm to the parents. This is usually owing to the mouth being wide open during sleep and causing the pharynx to be much irritated owing to the resulting dryness. The mother is apt to send for the doctor in the middle of the night in much anxiety thinking the child is undergoing what she calls a convulsion, but by the time he arrives all is again quiet. When the uvula is shortened or the adenoids removed the cough ceases. Enlarged tonsils will, of course, aggravate the above state of things. The above is a common cause of night cough.

(3) *Bronchiectasis*, too, accounts for a violent spasmodic fit until the contents of the cavity have been expectorated. It is of assistance to arrange that the child leans out of bed with his head lower than his pelvis and coughs into a vessel on the floor (if he can be induced not to swallow his sputum), the force of gravity being thus called into action, usually with satisfactory result. This cough commonly takes place in the morning on the child waking up after a period of sleep during which the cavity fills up.

(4) *Fibroid Lung* without cavity is also said to produce this kind of cough, but it is more probably due to dilated bronchi in some form or another also. The dilatation may well be cylindrical as opposed to the saccular form in bronchiectasis.

(5) Lastly, a *Foreign Body* in the air passages often causes a spasmodic cough, and this may be the only sign of its existence there. It may be therefore that the well-known trouble of ascertaining whether a foreign body has been swallowed or not will have to be undertaken.

(*b*) As to non-spasmodic cough, most of those caused by reflex actions due to nerve irritation in parts other than the lung, are usually dry, harsh and worrying to a greater or less degree. It must, however, be remembered that a cough may start in this way and yet may eventually produce some expectoration owing to the irritation of, and the increased secretion by the bronchi (induced by the mere action of coughing) which will reduce the harshness and dryness of the sound.

(1) Thus the cough attributed to the difficult eruption of the teeth is often accompanied by bronchial secretion of mucus, or, as some put it, the eruption of the teeth is a cause of bronchitis. Tooth irritation, however, is not admitted by all to be directly a cause, but it is asserted to be due to a true coincident bronchitis. It would, however, appear that this cough often subsides with the eruption of a tooth, having given needless anxiety.

(2) The hysterical cough is usually described as a sort of bark, which word best describes the sound in general. It is often accompanied by some definite muscular act or trick. I once saw a case where before the cough the child, a girl, æt. 11 years, smacked her tongue twice against the roof of her mouth. In these instances both the cough and the trick have to be cured by the will of the patient regaining sufficient control over the muscles involved. I cured this patient by telling her to close the lips tightly and blow against them when she felt the fit coming on. This stopped the tongue trick, and the cough, too, did not follow.

(3) A cough may often follow a specific fever such as measles or influenza, during the convalescence, and it is accounted for usually by talking of general debility. Probably it is due to a hyper-sensibility of the respiratory mucus membranes following the hyperæmia induced during the disease.

(4) Intestinal irritation from helminthic and other troubles is said to cause cough. It is not clear that this is the case. Gastric indigestion is more likely to be a cause, and cough is certainly caused by the more nearly physiological acts, such as commencing to vomit, or mere regurgitation in breast-fed babies.

(5) Irritation in the ear is also a probable cause, so that even hardened wax in the external meatus is said to be sufficient for the production of a cough.

(6) The cough of circulation troubles is well known, as in the case of mitral regurgitation or of pressure as in the case of mediastinal tumours.

(7) Dust or a smoky nursery have also been not unfrequently the cause of difficulty of diagnosis. This cough is commonest in particularly irritable mucous membranes, and this point should not be forgotten in all coughs: that the idiosyncrasies in degrees of irritability are very marked. What will produce a violent cough with streaming eyes, injected cheeks and great discomfort in one has no visible effect on another in the same nursery. The smoke of the fire when lighted in the morning may produce a cough for the rest of the day in one or two of a large family.

In conclusion, the mind of the practitioner in approaching this question should always begin by considering whether the cough is doing useful work, such as the removal of mucus from the lung or the expansion of it due to the effort and breathlessness involved. It should, on the other hand, be remembered that the irritation and violence of it may be out of all proportion to good work done. The latter is nearly always the case in those instances where the cough is not originated by the lung which we have been considering, and therefore there is more reason to treat them with sedatives, pending a removal of the cause.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Dr. Joseph Hollós, Szeged, Hungary. Subject: "Tuberculosis as a Cause of Menstrual Disturbances."*

ORIGINAL PAPERS.

THE PATHOLOGY OF THE VARIOUS ACUTE INFLAMMATIONS OF THE THROAT AND NECK, INCLUDING ACUTE ŒDEMA, PHLEGMON, ERYSIPELAS, AND ANGINA LUDOVICI, BUT EXCLUDING DIPHTHERIA. (a)

By PHILIP R. W. DE SANTI, F.R.C.S.ENG.,
Surgeon in Charge of Throat, Nose, and Ear Department, Westminster Hospital.

Summary.

THE paper is based on a report of four cases of acute septic inflammation of the throat with bacteriological examination, read before the Royal Medico-Chirurgical Society of London in 1903. This communication was a sequel to a paper read by Sir Felix Semon before the same society in 1895 on "The probable pathological identity of the various forms of acute septic inflammations of the throat and neck, hitherto described as acute œdema of the larynx, œdematous laryngitis, erysipelas of the pharynx and larynx, phlegmon of the pharynx and larynx, and angina Ludovici."

In addition, details are given of four more such cases, making in all eight cases.

The eight cases are:

1. Erysipelas of the pharynx.
2. Acute septic œdema of tonsils and pharynx.
3. Acute gangrenous inflammation of the throat.
4. Acute pharyngitis due to streptococcus pyogenes followed by septicæmia, deep glandular inflammation and pericarditis.
5. Acute suppurative inflammation of the larynx.
6. Acute œdematous septic laryngitis.
7. Acute septic inflammation of tonsils and pharynx.
8. Acute septic inflammation of pharynx, tonsils, and buccal mucous membrane, with inflammation of submaxillary cellular tissue.

All the cases were adults with one exception, a boy aged 12. All were of the male sex, in the prime of life and previously healthy. Five were hospital and three private cases. In all the streptococcus predominated in cover-glass preparations and on cultivation; six out of the eight cases were treated with some form of anti-streptococcus serum. One case had as well an autogenous vaccine. In one case the subsequent history is unknown, as the patient refused admission to the hospital. In one case serum and vaccine treatment was refused but the patient recovered. The six cases treated all made good recoveries, as also the one who refused serum treatment. The history, clinical symptoms, the course of the disease, and more particularly the bacteriological examination of this series of cases indicate their pathological identity and point to the conclusion that each case should be considered as showing merely a varying degree of virulence of one and the same pathological process. The micro-organism chiefly present as the causative factor is the streptococcus pyogenes group. Other organisms may be and are found: not infrequently more than one organism is present. There is, however, no one specific organism for any one of these various inflammations.

The different localisation of these septic inflammations depends on the resisting powers of the parts attacked, an accidental breach of surface or a pre-existing condition of catarrh rendering the part more susceptible to infection. The main points in treatment of these inflammations are early recognition, and the question of serum or vaccine treatment. A serum should be given early and of a type most nearly approaching the autogenous variety. Following the use of a serum or in combination with it (sensitised vaccine) an autogenous vaccine should be given as soon as prepared.

Under this title is included a number of forms of acute septic inflammations of the pharynx, larynx, and cellular tissue of the neck (angina Ludovici) which up to quite recently had been looked upon as pathologically and clinically different diseases: even to the present day confusion exists and most textbooks still describe "inflammatory œdema," "phlegmon," "gangrene and erysipelas," etc., of the pharynx and larynx as separate diseases.

In April, 1895, Sir F. Semon read a paper at the Royal Medico-Chirurgical Society of London on "The probable pathological identity of the various forms of acute septic inflammations of the throat and neck, hitherto described as acute œdema of the larynx, œdematous laryngitis, erysipelas of the pharynx and larynx, phlegmon of the pharynx and larynx, and angina Ludovici," and advanced the view mainly on clinical grounds that these various forms of acute septic inflammations of the throat and neck should be looked upon as varying degrees of virulence of one and the same pathological process, the primary seat and subsequent development depending in all probability on accidental breaches of the protective surfaces through which the pathogenic micro-organism causing the subsequent events found an entrance.

In February, 1903, I read before the same society a paper on "Four cases of acute septic inflammation of the throat with bacteriological examination of each," as a sequel to Sir Felix Semon's communication, and advanced proofs clinically and bacteriologically confirming Sir F. Semon's conclusions. Since reading my paper I have had experience of a few more cases, and as to-day's communication is based on these cases, I shall forthwith give as briefly as possible notes of each.

CASE I. *Erysipelas of the pharynx.*

Male, aged 48, deep-seated cervical abscess, right side of neck, due to a Bezold's perforation of mastoid; abscess in neck opened and radical mastoid operation performed. Some three weeks later during convalescence the temperature rose to 102.4, and cutaneous erysipelas was noted on the left cheek; this spread to the whole of the left side of the neck and face, then across the mid-line to the face and neck on the right side; there were patches of redness also all over the back extending to the lumbar region. Soreness of the throat was complained of and a swollen bright red condition noted of the post-pharyngeal wall and whole of soft palate and uvula.

Cultures from the throat showed mainly streptococci pyogenes with some staphylococci.

10 c.c. of a polyvalent anti-streptococcal serum was injected into the abdominal wall, followed by a second and a third injection on succeeding days. Reaction occurred at once, and shortly after the last injection all rash had gone and the throat was normal.

CASE II. *Acute œdematous tonsillitis and pharyngitis.*

Male, aged 32, history of three days' illness, *i.e.* headache, shivering, sickness, and for twenty-four hours pain and dryness of throat increasing rapidly.

Patient looked ill, voice a whisper, temperature 104.6, pulse rapid, 120, enlarged and tender glands both sides of neck. Some albumen in urine

Throat: intense redness and œdematous swelling of right tonsil, soft palate and uvula; dark red glazed and swollen condition of post-pharyngeal wall; slight œdema of the epiglottis.

Swab cultures from the tonsil and pharynx showed streptococcus pyogenes in numberless chains. The patient refused admission to the hospital and the further history is unknown.

(a) Independent paper read at the Section of Rhino-Laryngology, International Congress of Medicine, London, August, 1913.

CASE III. *Acute gangrenous inflammation of the throat.*

Male, æt. 21, sore throat, pain and difficulty in swallowing, loss of voice, and headache of two days' duration and rapidly getting worse. Previously very healthy. Temperature 101.2, pulse rapid and soft. Uvula much swollen, intensely red above, but lower half quite black and gangrenous. Soft palate red and œdematous and tonsils slightly so. Epiglottis slightly swollen. Extensive œdema of left aryepiglottic fold.

On admission patient could not swallow at all. Swab cultures from the uvula and pharynx revealed streptococci pyogenes, some staphylococci, no diphtheria bacilli.

At once 20 c.c. of anti-streptococcal serum was injected into right lumbar region, and pure carbolic acid rubbed carefully into the gangrenous uvula.

Five hours later the patient could swallow. Three days later the patient was rapidly recovering, and from then an uninterrupted recovery ensued. Only the one dose of serum was injected, as the improvement following was so very marked.

CASE IV. *Acute pharyngitis due to streptococcus pyogenes followed by septicæmia, deep glandular inflammation and pericarditis.*

Male æt. 21, first taken ill with sore throat and swelling in neck October 16th, got worse and was admitted into hospital October 24th, partly unconscious and almost moribund. Temperature 101.4, pulse 120, low tension, severe precordial pain. Tongue swollen and brown, posterior pharyngeal wall very swollen, darkish brown and some sticky mucus. Mouth difficult to open; large brawny red swelling left side of neck.

Auscultation: loud pericardial friction rub. The swelling in neck had been incised but only a little sanious fluid escaped. Mucus from throat and discharge from cervical wound showed mainly in coverglass specimens, and upon cultivation, streptococci pyogenes. A yeast, staphylococci albus, and a few bacilli were also found on cultivation of the mucus from the throat.

10 c.c. of anti-streptococcal serum injected at 9.30 p.m., at 8 a.m., and 4.20 p.m., next day, and a fourth dose on the following day. Patient began to rally at once although not expected to live through the night and made an excellent recovery.

CASE V. *Acute suppurative inflammation of the larynx.*

Male, æt. 47, a private patient in previously excellent health. Sudden onset with chill, malaise and intense pain in the throat: temperature 102.4, pulse 110, soft; within 24 hours of onset difficulty in breathing and swallowing.

When I saw the patient 48 hours after the first onset of disease, I found him very ill with dyspnœa, constant bad cough, and bringing up a lot of mucus and pus; the temperature was 102.6, the patient was cyanosed; pulse rapid and small, anxious look. The pharynx was slightly congested; examination of the larynx showed very considerable acute œdema of the arytenoids, inter-arytenoid space and aryepiglottic folds and all the larynx was more or less bathed in pus. No tenderness of larynx externally.

20 c.c. of polyvalent anti-streptococcal serum injected at once and preparations made for emergency tracheotomy. Within 12 hours there was a marked change for the better; temperature 100.8; muco-pus diminishing and breathing easier; patient made a rapid recovery. The pus from the larynx on cultivation showed pure streptococcus longus.

CASE VI. *Acute œdematous septic laryngitis in a boy of 12.*

Patient was a boarder at a large private school. There had been one case of diphtheria in the school seven weeks previously. The illness began with headache, lassitude, sickness, and some sore throat and a temperature of 101.3.

Patient was isolated, and swabs taken from the throat and nose; no diphtheria bacilli were found, but staphylococci and streptococci were present. Twenty-four hours later patient was much worse, the throat trouble being laryngeal.

I saw the patient late in the evening and found very embarrassed breathing, recession of chest and mucopurulent matter being coughed up.

Examination showed nil in pharynx, but considerable œdema and redness of the epiglottis and posterior region of the larynx; the swollen parts were covered with pus, no sign anywhere of membrane. Temperature 102.6; anxious appearance; sweating; rapid pulse. 10 c.c. of polyvalent anti-streptococcal serum injected into buttock; patient easier 6 hours later, and temperature 101.4; a second injection given 12 hours after the first; good recovery.

CASE VII. *Case of acute septic tonsillitis and pharyngitis.*

Male, æt. 32, private patient, illness taken to be an ordinary double quinsy; three days after commencement of attack patient seemed very ill and general condition getting worse. I saw him in consultation and found intense sloughy suppurative inflammation of left tonsil and œdematous swelling of post-pharyngeal wall and opposite tonsil; temperature 101.4; painful deglutition; anxious look; trace of albumen in urine, ordinary remedies had had no effect.

I advised immediate injection of anti-streptococcal serum to be followed by an autogenous vaccine, but patient refused this line of treatment. He was treated with large doses of perchloride of iron, and although his convalescence was protracted he got quite well.

Cultures from pus over left tonsil revealed almost pure streptococcus longus.

CASE VIII. *Acute septic inflammation of pharynx, tonsils, and buccal mucous membrane, with inflammation of submaxillary cellular tissue.*

The patient was a chef and a drinker. When seen by me he had considerable swelling and œdema of the pharynx and tonsils and buccal mucous membrane on right side; there was an abscess round a carious right upper molar tooth.

The submaxillary region of neck on both sides was swollen, hard, and tender, and the floor of the mouth œdematous and prominent; lower and upper lips much swollen. Temperature 101.6. Patient was admitted into hospital, the tooth seen to, and 20 c.c. of polyvalent anti-streptococcal serum injected. An autogenous vaccine was prepared from cultures taken from the throat, mixed organisms being found. He reacted within a few hours and made a rapid recovery.

The submaxillary inflammation yielding at once to the serum did not require incisions. I was prepared in this case to give citric acid internally if necessary as recommended by Sir A. Wright.

Now, in my opinion, the history, clinical symptoms, the course of the disease, and more particularly the bacteriological examination of my cases, all point decisively to their pathological identity, and to the conclusion that each case should be considered as showing a merely varying degree of virulence of one and the same pathological process.

Since the reading of Semon's paper in 1895, great strides have been made in bacteriological research, and it is mainly on bacteriological grounds that one has to discuss these acute septic inflammations.

It is now universally acknowledged that these infections are due to the invasion of the system by pathogenic organisms, of which at all events in my experience the streptococcus pyogenes group is far the most important and frequent. Other organisms may be and are found, especially the staphylococcus aureus, albus, and citreus, pneumococcus, bacillus coli communis, and micrococcus tenuis, and should any one of these micro-organisms multiply sufficiently, then an acute septic inflammation may be produced which can only be differentiated from a streptococcal inflammation by bacteriological examination. There is, however, no one specific organism for any one of these various inflammations; not infrequently more than one organism is present.

Again, the same organism, especially the streptococcus pyogenes, may produce widely varying results under different circumstances, at one time a local inflammation, in another erysipelas, in another an abscess, cellulitis or a general septicæmia (Marmorek's experiments); this is well exemplified in my series of cases, in all of which the streptococcus predominated, and yet in some cases there was so-called acute phlegmon, in others suppuration, erysipelas, and gangrene.

Formerly streptococcus pyogenes and streptococcus erysipelatis were considered as two different species, but it is now universally agreed that the two organisms are one and the same, erysipelas being produced when the streptococcus pyogenes of a certain standard of virulence gains entrance to the skin lymphatics.

These different effects, then, are attributable partly to differences in virulence and the number of micro-organisms gaining access, partly to the seat of infection and mode of entry into the body, partly to the resistance of the individual, and partly to real differences existing between different races of streptococci. Poynton believes there is another factor, viz., a tendency inherent in micro-organisms to produce special poisons, a specific toxicity which has to be reckoned with in all investigations on the unity of the streptococcal group.

Staphylococci usually and streptococci often can be cultivated from the secretions of the mouth in normal conditions. Fraenkel's pneumococcus and the pneumobacillus of Friedlander have also been found in the mouth and nasal cavity: the entrance of these organisms into the deeper tissues when a surface lesion occurs can easily be understood. The objection urged that the different localisation of these cases spoke against their being identical is wrong. The different localisation of these septic inflammations depends on the resisting powers of the parts attacked, an accidental breach of surface or a pre-existing condition of catarrh rendering the part more susceptible to infection.

As Semon has pointed out, diphtheria remains diphtheria whether it primarily attacks the throat, nose, conjunctiva, or vulva, and it is the same with these acute septic inflammations of the throat.

In my experience Ludwig's angina should be included in this class of case. It is a variety of submaxillary cellulitis, an acute suppurative sometimes gangrenous periglandular inflammation in the region of the submaxillary glands, and the infection usually occurs from a lesion of the oral buccal mucous membrane, from a carious tooth or perhaps inflamed tonsil. It is commonest in males of 20–30.

It is always very sudden and rapid in its course, the swelling at first very hard and brawny, pushing up the tongue and causing protrusion of the submental tissue. It is a particularly dangerous variety and requires very prompt surgical measures in addition to other treatment. I might mention here the use of citric acid internally. In a case seen by Sir A. Wright of Ludwig's angina in which multiple incisions had been made early, the patient 24 hours later was collapsed and delirious: none of the gaping incisions showed any moisture. Film preparations showed abundant streptococci; the blood taken from a vein at the elbow clotted at once. Wright prescribed 60 grs. of citric acid every 3 hours: 6 hours later lymph began to ooze from the wounds and the acid was stopped. Improvement was so rapid that no vaccine was employed and there was complete recovery; other such cases have been recorded.

The citric acid lowers the coagulability of the blood so that lymph containing large amounts of anti-bacterial and anti-tryptic bodies are freely admitted to the infected parts and the organisms thereby destroyed before the formation of pus. *Clinically* in these cases of acute septic inflammation of the throat the following points are noteworthy. That the patients are usually adults, mostly men in the prime of life, in excellent previous health, and frequently as in Semon's cases of the higher social scale. In my cases, however, five were hospital and three private patients of good social standing.

That it is most important to recognise early the nature of the case and whether local or constitutional treatment is the most urgent with regard to treatment. That as Dundas Grant has pointed out, sore throat and general bodily illness, a voice suggesting peritonsillar abscess, but ability to open the mouth, and nothing much to be seen in the throat, are conditions dangerous to life. Finally, the question of serum and vaccine therapy has a considerable bearing on the pathology of these diseases.

In 1903 I advocated strongly the immediate intramuscular injection of 10-20 c.c. of anti-streptococcal serum and pointed out that all my cases had done remarkably well under that treatment. In my subsequent cases I have had equally good results from the same treatment, my cases being mainly at all events of streptococcal origin. The last few years, however, vaccine therapy has come into fashion, and the tendency in these cases is to use an autogenous or still more recently a sensitised vaccine. In only one of my cases was an autogenous vaccine employed, and prior to its use an anti-streptococcal vaccine was used. These streptococcal infections are primarily local, some becoming permanently circumscribed, others giving rise to septic and pyæmic conditions. Ball, in his lecture on "Acute infective processes due to the streptococcus" (*Lancet*, 1912, vol. i), emphasises the following points in regard to serum and vaccine therapy.

That the blood should be examined.

In all cases probably of streptococcal infection a certain number of bacteria do get into the blood-stream though their presence cannot be demonstrated by the usual methods. In others they get the upper hand and can easily be demonstrated in the blood-stream. A streptococcus isolated from the blood is probably more virulent than that got from a local focus and therefore of more use in preparing a vaccine. There being many types of streptococcus an autogenous vaccine is of more use than a stock vaccine. That the object of *serum* therapy is to neutralise the toxins produced by bacteria by providing for the human tissues anti-bodies in larger quantities than they themselves possess, and is mostly of use in the early stages of infection. That the object of *vaccine* therapy is to stimulate the human tissues to produce anti-bodies for themselves. That the value of a vaccine on the temperature is shown in favourable cases by its fal to the normal by crisis within 24 to 48 hours after a single inoculation; in other cases with a second or third inoculation. That in approaching a case of infection due to the streptococcus:

(*a*) The clinical diagnosis should be accurate to the smallest detail, both as regards local and general symptoms, and the help of the bacteriologist sought in all cases.

(*b*) The lesion if necessary should be dealt with surgically and the necessity for use of artificial methods of stimulation of the machinery of resistance be then discussed.

(*c*) A serum should be given as early as possible and a type used that most nearly approaches the autogenous variety. Following the use of the serum or in combination with it (sensitised vaccine) inject an autogenous vaccine as soon as prepared.

(*d*) Dosage: no absolute rule. If seen very early the general condition being good and the focus of infection circumscribed, a relatively large dose of vaccine may be given, otherwise a small dose is indicated as an initial inoculation. If no effect is produced by the smaller dose gradually increase it until such a result is reached which will produce the desired reaction. If a harmful effect follows, a smaller dose is indicated or even vaccine therapy be contra-indicated.

NOTES ON

A CASE OF POLYARTICULAR RHEUMATISM TREATED BY RHEUMATISM PHYLACOGEN.

By W. ROSSELL JUDD, M.R.C.S., L.R.C.P.,
Ashton-under-Lyne.

The practitioner who has closely followed the many interesting papers published upon rheumatoid arthritis during the past decade must have been more than perplexed by the diverse opinions as to its origin, pathology, and treatment—opinions freely expressed by the highest authorities in the medical profession—so that as hypothesis followed hypothesis in each instance the position felt was that *se non è vero è ben trovato*.

For years we felt very comfortable in assuring our patients that an excess of uric acid was the *bête noir* of their affliction, but now confusion is confounded by an imperfect nomenclature and a war between defective metabolism and the products of microbic toxins. The general practitioner whose time is limited for independent investigation has therefore to follow the light shed by the many scientific lanterns in vogue.

The rapid changes which my patient underwent for the better during three weeks of phylacogen treatment form my excuse for publishing the subjoined notes, especially since for the past seven years she has undergone each treatment for the moment in fashion.

Mrs. H. A., æt. 36, married, four children. With the exception of an attack of pneumonia when 20 years of age, patient enjoyed good health up to seven years ago, when rheumatism set in in the left hip-joint; subsequently the right hip-joint was affected, then all the large joints of the body, and 3½ years ago the meta-tarsal, meta-carpal and phalangeal joints also became involved. For the past 3½ years the patient has been quite unable to get about, has lain in bed unable to feed herself, and having to be turned over when a change of position was felt to be necessary.

During the past seven years she has been under my care, and during this period she has swallowed enormous quantities of salicylates, iodides and guaiacol carbonate, whilst, also, free use has been made of oral and vaginal antiseptics, massage and electricity. Twice she has been to Buxton, and there obtained some slight, but temporary, relief.

Condition prior to treatment.—The patient lay in bed in a helpless condition, very anæmic and emaciated, with all her joints much enlarged, likewise rigid, the forearm flexed (semi-) on arm, legs extended (patient unable to flex them), and the lumbo-sacral joint rigid (unable to flex trunk on legs). Cardiovascular system revealed a soft systolic murmur at the apex. Blood vessels slightly thickened, blood pressure slightly above the normal, urine contains a slight quantity of albumin.

The first injection of rheumatism phylacogen (2 c.c.) was given over the right deltoid on July 23rd, at 1 p.m. Four hours afterwards reaction began, and six hours after the injection the patient was flushed, temperature was 102° F., respiration was rapid (34), there was dyspnœa, a burning at the seat of injection, alternate hot and cold sensations accompanied by nausea.

Daily injections were given, the dose being increased by 1 c.c. each time, and the seat of injection was varied, though selected as near as possible to the affected joints. After the maximum dose of 10 c.c. had been reached, six further injections of that amount were given.

Progress of injections.

After the third injection the pain became less, so that the patient was able to sleep; subsequently it ceased altogether, and it has not reappeared up to the present.

After the fifth injection an erythematous rash broke out within twelve hours; it practically covered the body, but it had disappeared by the next day.

After the sixth injection the patient could extend her arm and made very good attempts at sitting up in bed (without pain).

After the seventh injection she could move her legs, flex knee-joints, move the arms freely and could feed herself.

After the eighth injection (first maximum dose of 10 c.c.) the reaction was very severe—why this should have been so I cannot explain, since one would have thought that by this time the tissues were becoming accustomed to the phylacogen. To a certain extent the cause may have been psychical, since I informed the patient that she was having a large dose. The patient was very hot and restless, with a temperature of 104.6°, she was somewhat delirious, but could easily be roused from this condition, respiration was 44, with dyspnœa, pulse was 120. On the next day the patient felt exhausted, but her temperature was normal, and thereafter she gradually improved.

Comments.

This is, perhaps, one of the worst conditions on which to try this treatment, for the best results are obtained in acute and subacute cases; in fact the ultimate result in the latter is almost magical. I had made up my mind that if reactions failed to appear after the third injection I should abandon the treatment; fortunately a slight reaction was evident from the very first, and this induced me to continue. Nearly five months have elapsed since the last dose of phylacogen was injected; the patient is free from pain, sleeps well, has increased in weight, and can walk slowly.

SOME EXPERIMENTS ON REVIVIFICATION.

By ANGELO DE DOMINICIS, M.D.

My experiments based upon drowning in oxygenated water (hydrogen peroxide) have proved that animals can show vital signs for a time as much as three times longer than they can do in ordinary water. Taking into account the fact that the extension of time applied not only to the period of terminal respiration, but also to that of special asphyxia, I assumed that they could withstand the lack of oxygen for a corresponding period in connection with the determination of the asphyctic phenomenology.

Further experiments accomplished on newly born animals (kittens), whose remarkable resistance to asphyxia is well known, have given concordant results, and in fact it has been possible to observe vital manifestations extending over three hours.

Seeing that the penetration into the circulation of the oxygenated water (hydrogen peroxide) so plainly protracted life, we wondered whether an endotracheal injection could eventually show an influence also on the return of the vital manifestations, more especially when it is performed immediately after the stopping of the respiration.

In every way, on well-known physiological grounds, the injections of oxygen have been advocated, and among the more recent means of effecting it, I will recall the subcutaneous and the intravenous injections in the instance of intoxication by carbon monoxide; but it is obviously only the endotracheal method by which pulmonary absorption in certain conditions, and acting through the smaller circulation, can effect a greater and sufficient action on the general circulation.

Besides, one need not fear, as my experiments on rabbits and guinea-pigs have shown, near or remote inconveniences deriving from this way of introduction, which is not new, but certainly less used.

We use the Perhydrol (Merk) 1 : 10—that is to say, a solution at 1½% in the quantity of about one cubic centimetre per kilo, and even in larger quantities in small animals.

Among the positive experiments that I can show now, I wish to call attention to those accomplished on rabbits and on guinea-pigs, in rapid intoxication by carbon monoxide through illuminating gas.

After the corneal insensibility, the pupillary dilatation, the general relaxation, and the complete stoppage of respiratory terminal movements, while

---

(a) Paper read at the Section of Forensic Medicine at the International Congress in London, August, 1913.

the heart still pulsates, however, the injection of oxygenated water (hydrogen peroxide) into the trachea, accomplished with the utmost rapidity, is followed by thorax compressions (to facilitate the diffusion of the liquid into the lungs) and afterwards also by the lowering of the head to favour the flow of the arterialised blood into the nervous centres.

My experiments do not show, however, that these manœuvres may be usefully protracted for more than half an hour.

When the operation has been made very quickly and the experiment has been successful, one can assist the return of the respiration, first in the form of deep and infrequent respirations, and then as dyspnœa. The animals soon recover, however, without any subsequent ill effects appearing from the operation.

Undoubtedly numerous objections can be raised to these researches. By the thorax compressions there come into action artificial respiration and the mechanical stimulation of the heart, and there is yet the introduction of liquid into the circulation, while, on the other hand, through the necessary rapidity of the intervention, it may be difficult to exclude absolutely—in a particular instance—the possibility of the return of the vital manifestations, even without a special influence of the oxygenated water (hydrogen peroxide).

It seems to us, however, that these objections collide against some proved facts, even without considering the controlling experiments.

Even in the animals in which the cardiac contractions continue and the thorax is opened, the endotracheal injection of oxygenated water (hydrogen peroxide) will hasten the pulsations and increase the vitality of the cardiac impulse, at the same time that the heart gets filled and the oxygenated water enters into its cavities.

After this, it must be assumed that the oxygenated water (hydrogen peroxide) by endotracheal injection is also a good means of strengthening the cardiac activity, and as we know that the increasing of this power means increased chances of connecting the vital tripod, there cannot be the least doubt but that—be it even in special cases—the injections of oxygenated water in the trachea may conduce to revivification.

However, it is not beyond the practical possibilities, that in a case in which the heart still pulsates, one cannot succeed in restoring life.

Further researches in this direction, taking into account the physiological basis and the harmlessness of the intervention, will logically cause these experiments to be extended, besides affording more specific indications for cases allied to those which are referred to in the present note.

OPERATING THEATRES.

ST. THOMAS'S HOSPITAL.

Partial Separation of the Upper Epiphysis of the Femur—Hæmarthrus.—Mr. Edred M. Corner operated on a boy, æt. 15, who had fallen while riding his bicycle and sustained an injury to his right hip. He took no notice of it at the time, but a fortnight later he found that the joint was becoming painful. He managed, however, to continue his occupation of house-boy for another three weeks, when, coming downstairs one morning, his leg suddenly gave way, and he found himself completely unable to move it again. He was brought up to St. Thomas's Hospital, where he was examined and thought to be suffering from acute epiphysitis following on previous separation of the epiphysis. The limb was slightly flexed, with marked eversion. Any attempt at movement caused great pain. Temperature was 101° and pulse 100.

An open operation was performed the same night, and the joint exposed through Murphy's incision. The capsule of the joint was found to be œdematous, and the joint itself was filled with old dark blood. No actual pus was seen. There was a partial separation of the epiphysis, which was, at the time of operation, firmly joined to the shaft, except at one point, where the neighbouring bone was eroded. The blood was removed. The wound was stitched up in the usual manner, the wound being drained for two days. At first the limb was put in extension, a long outside splint being applied to the sound side. Later this was discarded for a Style's splint.

Ten days after the operation everything was going on satisfactorily. Mr. Corner said it was intended to keep the splint on for about six months before allowing free exercise of the joint.

Mr. Corner remarked that the great clinical difficulty was that of diagnosis. The boy was thought to have an acute arthritis of the hip-joint. In reality he had in part separated and displaced the upper epiphysis of his femur some time before, and now had an auto-infection of the blood in his joint—hæmarthrus. On seeing the case for the first time, Mr. Corner did not know this. The factor of greatest clinical service was, he pointed out, the operation of exposing the hip-joint by detaching the tip of the great trochanter. The exposure of the joint was so good as to allow the surgeon to see with ease the displacement of the epiphysis. Moreover, it could be ascertained that union had already occurred between the epiphysis and the diaphysis. Therefore there was no need to unite them as by a screw.

A case of Arthroplasty of Hip.—The same surgeon operated on a girl, æt. 16. In March, 1910, the patient fell on her right hip which later (May) became painful, later becoming stiff. A skiagraph showed no evidence of injury to bone, so that the ankylosis was due to some form of arthritis. The operation was performed at a meeting of the International Medical Congress. After separation of the bones it was seen that some cartilage still existed on the head of the femur. The acetabulum was then cleared and covered by a piece of fascia lata. The head of the femur was then replaced in the joint. Ten days after operation with unaided efforts the girl comfortably flexed the hip through 90 degrees. Subsequently to leaving the hospital she had a lot of pain in the new hip joint, which it was feared would lead to limitation, perhaps only temporary, of its movements.

CHILDREN'S HOSPITAL, GREAT ORMOND STREET.

Case in which the Approach to the Hip Joint by Detaching the Tip of the Trochanter enabled the Surgeon to make a new Hip Joint, a Nearthrosis, successfully.—The case operated on was that of a little girl, æt. 5, with old tuberculous disease of both hips, many operations, unilateral arthroplasty. She had bony ankylosis of the right hip and fibrous ankylosis of the left hip. There was a little movement in the left hip. Neither hip could be abducted easily, and she had previously been in the hospital for crossed adducted legs. The legs were then separated by "extensions" to each side of the bed. But the condition recurred doubtless owing to the mechanical advantage which the adductors have over the abductors. It was decided to do an arthroplasty on the right hip joint, so that by making that a free joint the condition could be relieved. The operation was done as here advocated with a fascia flap placed in the acetabulum and a covering of Baer's membrane on the head of the femur. Mr. Corner said that the success of operation for one ankylosed hip, when both are ankylosed, gives the patient so much relief that no operation may even be required on the other side. He pointed out that this case illustrated what is the greatest bar to perfect success of arthroplasty in growing subjects where the hip has been "out" for some time. The upper end of the femur becomes twisted forwards as it grows against the side of the pelvis. The new joint is made first and a sub-trochanteric osteotomy is done later.

TRANSACTIONS OF SOCIETIES.

THE NEW LONDON DERMATOLOGICAL SOCIETY.

Meeting held Thursday, December 11th, 1913.

The President, Dr. David Walsh, in the chair.

The President showed a case of an acute generalised coccic dermatitis treated with an autogenous vaccine.

C. D., æt. 42, m., stationer's assistant, came to hospital, October 21st, complaining of an irritating rash that began on hands about three weeks previously and is now generalising. The hands were dusky red, swollen and desquamating in thick flakes on the palms; the arms were swollen, red and desquamating. The trunk covered with patches and sheets of fine papulous rash. Patient said rash was sometimes moist and the discharge stiffened linen. Twenty years ago he had inflammation of the lungs and pleurisy. There was not much general disturbance, but the patient looked the picture of misery, as he had slept but little, owing to the irritation. There were some irregular superficial ulcers near the left ankle. He was practically bald on the upper part of scalp, and the rash affected scalp and face. He walked lame as the result of the dermatitis around knee and altogether was the picture of misery. Ordinary soothing and antiseptic remedies with quinine internally had little effect.

A pure culture was obtained by the Hospital Pathologist, Dr. D. Benjafield, of staphylococcus aureus from a bleb on the back of the hand. The first dose of 50,000 was given on November 5th. Immediate improvement followed. On 12th, 100 million; on 19th, 150 million; patient did not come next week, but on getting rather worse returned, and on December 3rd had 200 millions; on December 10th he was given 250 million. The improvement was rapid and progressive—the ulcers on the legs healed—the rash faded and the patient was—as he expressed it—like another man.

There was a history of chronic dyspepsia; but no palpitation nor dyspnœa. There were no valvular murmurs; but the arteries at wrist showed moderate arterio-sclerosis.

The case shows in a striking way the value of an autogenous vaccine on a severe dermatitis. My thanks are due to Dr. Benjafield for his care of the patient.

Dr. Alfred Eddowes showed a case of acne possessing some special points of interest. The patient, a healthy man, æt. 46, stated that ten years ago he observed several points like little boils on his forehead. He went to and attended for a long time a well-known skin hospital in London, and afterwards consulted doctors in private, but only obtained temporary improvement. He was becoming pitted all over the face as if by small scars of small-pox. When he came under Dr. Eddowes' care a few weeks ago many lesions were present, and they all had essentially the same character. They were neither cystic nor like the ordinary acne punctata, but were firm, almost hemispherical; not actively inflamed nor obviously suppurating; always umbilicated and showed a remarkable resemblance to a small, slowly developing molluscum contagiosum papules. In fact it might be termed a molluscoid acne or folliculitis. Their resistance to remedies was great, so to overcome that a treatment was adopted which the exhibitor strongly recommended in such cases—viz., the introduction of a droplet of pure liquefied phenol by means of the eye of a fine darning needle. Cultures showed staphylococcus aureus and a short-chain streptococcus.

The President considered it was a varioloid condition, with scanty lesions, exceedingly chronic and rebellious to treatment.

Dr. Norman Meachen showed a case of dermatitis verrucosa in a cowman, æt. 49, who had had a lesion on the back of his right hand for four months. It began as a small, roughened area, which the patient called a wart. It spread towards the wrist, and he thought it had a fungous origin. It was covered by small granular papillary excrescences, from which a sanious discharge exuded on squeezing. He had made a search for the blastomyces, but hitherto without result. There was no family history of tuberculosis. The axillary glands were slightly enlarged, and the femoral glands were palpable.

The President suggested that Dr. Meachen should report again later. He remembered a similar case in a butcher, who had it on the site of an accident with a meat hook. It was found to be due to a fungus.

Dr. Eddowes regarded it as a *post-mortem* wart verruca necrogenica. He had treated and watched such cases in butchers many years ago, and before he was aware they were due to tubercular infection he was in the habit of painting them with strong carbolic acid and then poulticing them. The result was satisfactory.

Dr. Samuel said Biersdorf's salicylic and creosote plasters (No. 78) cleared these conditions of lupus verrucosus up remarkably well without any additional treatment. The physical signs here fitted in with the pictures of blastomycosis, but he felt that for all that our old friend the tubercle bacillus was just teasing us once more.

Dr. C. G. Mack said he regarded the enlarged glands in the axilla as tubercular.

Dr. Meachen replied that there was no history of tubercle in the family, and the patient was a healthy man. Four months would be a short history for a tubercular lesion, and in spite of the negative findings it resembled fungous disease more than tubercle. He would report later.

Dr. H. C. Samuel showed (1) seborrhœa on a syphilitic basis, or rather syphilis on seborrhœic soil. The patient, a man æt. 64, came to University College Hospital that day. It was diagnosed a year ago as psoriasis, and subsequently scars and pigmentation were seen at the axillæ, which were certainly syphilitic. Wassermann was positive. The lesions cleared up under the usual treatment, and since then attention has been devoted to the seborrhœic condition. He had developed some new lesions on the back which looked like circinate seborrhœa: seborrhœic dermatitis; they, however, seemed more infiltrated than ordinary seborrhœa. There was also atrophy on the back of his hands, so-called "tropical skin," with pigmentation, but he had never been in the tropics. He has other evidence of tertiary syphilis, but the circinate follicular lesions on the back are in typical situation, and have the typical colour and general appearance of seborrhœic dermatitis (so-called lichen circinatus or circumscriptus).

The President said he did not see why it should not be seborrhœa on a syphilitic basis, a suggestion that was borne out by the scarring on one of the patches near the left knee. Dr. Norman Walker believed that seborrhœa was the starting point of many syphilitic lesions, and he agreed. There probably was good reason for these localisations.

Dr. Samuel replied that so many of the manifestations of disease seen depended on the type of patient. A patient the subject of acne who caught syphilis would develop acneiform syphilis. Others again who were liable to psoriasis or seborrhœic dermatitis would, if they contracted syphilis, tend to show types of syphilitic rashes, which were of a seborrhœic or psoriasiform type, and so on.

(2) CASE OF LUPUS ERYTHEMATOSUS TREATED BY UNNA'S MICROBRENNER.

The patient, a man, had had the condition of his face 16 months. The lesions consist of erythematous patches with grey (mortar like) adhesive scales, and some thin superficial scarring. The case was very rebellious to treatment; he had received all the usual internal and external treatments, including salicin quin. internally, and locally such applications as lotio calaminæ, the solid stick of CO_2 snow, and the solution of CO_2 in acetone. Yet for some reason or other the disease failed to clear up. So one tried the effect of soft soap dressings, as recommended by Hebra—this again proved futile—recently one has been utilising Unna's microbrenner, touching the parts lightly here and there, and although so far this treatment has yielded the best results and has had the effect of limiting the spread, yet one is not satisfied, and we propose treating it with the Kromayer lamp (mercury vapour), which in these chronic cases is the last card, and generally a trump card which rarely fails. I show the case to demonstrate the exception (which proves the rule) that CO_2 snow is not *always* the specific for these chronic cases of lupus erythematosus which it] is claimed to be.

The President asked whether syphilis and tuberculosis had been excluded. He deprecated Dr. Samuel's strong views about the Von Pirquet reaction. He, Dr. Walsh, would be sorry to be without Von Pirquet, despite its fallacies. He would not hesitate to use tuberculin after excluding gross pulmonary tuberculosis, which could be done by ordinary careful examination.

Dr. Norman Meachen said care should be taken in applying to any form of treatment the term "specific." He believed the word had been used concerning the use of CO_2 for lupus erythematosus. It was specific simply in producing a local reaction, and by aiding the production of anti-bodies. If one exceeded that a destructive lesion and scarring ensued. The best way of using the snow for this condition was by lightly touching with the crayon for not more than twenty seconds at a time. But he would not call it a specific treatment.

Dr. Samuel replied that he did not mean that CO_2 snow was specific in the strict literal sense, but that in chronic cases the local application of CO_2 was one of the best to use, and he only used the snow in chronic cases. He agreed only short applications should be made, sufficient to produce that local reaction which would assist the patient to combat the disease; not with the object of destroying the structure. A *negative* Von Pirquet in the adult was important, as it showed there was no tubercle elsewhere. Most people had had tubercle at some period, and it was not surprising that in 70 to 80 per cent. of adults the Von Pirquet was positive, though there might be no active tubercle. The test had not been done in the present case because he had no faith in it. Syphilis had not occurred to him; if it had been that disease there would have been more destruction and scarring by this time.

(3) CASE OF LEUCOPLAKIA OF TONGUE CURED BY REMOVAL OF TEETH.

The patient was a middle-aged woman, in whom leukoplakia appeared four months ago. The condition was thought to be probably specific, but it did not respond to potassium iodide or salvarsan, and the Wassermann was negative. She suffered severely from pyorrhœa and dental caries, and after the removal of the teeth the leucoplakia had cleared up. The leucoplakia was so advanced that it was difficult to believe that the teeth were the only factor in the case, and one could not resist still holding the syphilitic theory—but after the teeth were removed and artificial ones restored the whole of the advanced and painful leucoplakia disappeared.

The President said that dentists had not yet found a scientific treatment for pyorrhœa. In this case the result of removal of the teeth was very striking. Moreover, in a woman of this age, to clear up her leucoplakia was a very important matter, on account of the possibility of malignant developments.

Dr. Vinrace wished to raise a protest against such a wholesale removal of teeth for such a cause. Some people handed over patients to the dentist to be converted into edentate monsters on very slight data. He would like to know whether any measures were taken to preserve the teeth instead of removing them.

Dr. Samuel replied that Dr. Vinrace's remarks would have been modified considerably if he had seen the condition of the woman's mouth when she was first shown.

Dr. Vinrace showed (1) a case of tertiary syphilis in a woman æt. 52. Her first pregnancy, at æt. 18, was a miscarriage. She had an ulceration on her foot four years after, viz., thirty years ago, and it healed up; but it broke out again 3½ years ago, and only healed after 18 months' treatment with iodide of potassium. Twelve months' recent treatment, including mercury and iodide of potassium and 0.1 gramme of salvarsan hypodermically on November 21st had made no difference to the lesions on the dorsa of the feet which had been persistently raw, scaly and foliaceous. Salvarsan he was abandoning because it produced such severe local reaction. If the Wassermann test proved positive, he intended to give salvarsan intravenously.

The President considered that the salvarsan was given in too small a dose. He did not consider that iodide of potassium and the ordinary treatment would be of any use in such cases.

(2) Case of telangiectasis and scarring of the face in a barman. At the present time some active lesions, probably staphylococcic. Nine years ago he had "barbers' rash." If members had seen the case from a medico-legal aspect what would they say the scarring was due to? And would they say the telangiectases were due to the cutaneous condition, or incidental to the man's occupation as a barman?

The President said the condition was like the scarring left by acne. He did not know what the telangiectasis meant, except that it was probably connected with alcohol, bearing in mind the patient's occupation. The mitral sound was somewhat abnormal. He recommended treatment by an autogenous vaccine.

Dr. H. Eddowes said that telangiectasis on the face could be produced if enough follicles or glands were distributed in the acne process, because if they were swollen and crowded together, they interfered with the venous return by the radical (vertical) veins leading from the papillary layer.

Dr. H. C. Samuel suggested that the condition might be associated with some cirrhosis of the liver.

Mr. T. P. Beddoes showed a case of keratosis of the palms in a man, of ten years' duration. A marked feature was the manner in which the sweat pores were attacked.

The President said Mr. Beddoes was fortunate in getting a patient at hospital with that condition. Though he had had the affection two years it caused him no physical discomfort.

Dr. Eddowes said it was particularly interesting to see a disease attacking the sweat pores in this manner so sharply defined. He thought dermatologists had paid too exclusive attention to follicular infection, and were inclined to forget the many possibilities of infection of the sweat apparatus. In the case before them there was almost certainly some infective material in the pores. He would relate a case showing how a man's palm had become infected with organisms which had lain hidden there probably for some years. It was a case seen by the late Dr. Crocker, that of a gardener who had an inflammation of one hand spreading like erysipelas and causing much swelling and pain. The attacks occurred summer after summer. Dr. Eddowes saw the man in the third attack. The condition was soon improved by treatment, but recurred during succeeding hot weather. He had dressed the hands with antiseptics in such a way that it was impossible to see how germs could get into the palm of the hand while the parts were so thoroughly protected by the enveloping dressing. One day on removing the dressing a small abscess could be seen in the centre of the palm. This was punctured and yielded a beautiful, deep-coloured pure culture of staphylococcus aureus. The speaker believed that organisms on getting into the sweat pores met with acid material which did not suit them; they were not killed but were rendered inactive. There was nothing in the pores to encourage the growth of these organisms until something was added, such as an effusion of serum, which by neutralising the acid converted the moisture into a culture medium when, of course, irritation might be lighted up through the formation of toxins. He believed he was the first in this country to call attention to plantar warts. Now we know that warts are due to infection. If that infection were not introduced by a gross lesion, such as a scratch or other wound the germs must enter by way of the pores there being no follicles present.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, December 5th, 1913.

The President, J. F. O'Carroll, M.D., F.R.C.P.I., in the Chair.

A CASE OF RAYNAUD'S DISEASE.

Dr. Drury showed a man, æt. 32, who had this disease. He had been in India. Two years ago he was engaged as a night porter. At the beginning of the present winter the disease began in his hands. When first seen four weeks ago his right hand was in a condition of local asphyxia and the other hand showed a commencing gangrene, the whole hand being blue and intensely cold. He never permitted the patient to wash his hands, fearing sepsis. There was no albumen or sugar in the urine, and he gave a negative Wassermann. The condition came on quite quickly, and its acute course was of interest. No pulse could be felt in the left wrist, and in the right it was scarcely perceptible. He was treated with alcohol and chloride of calcium, first five and then ten grain doses per diem. There was much pain at the beginning, and opium had to be administered at night. The patient was at work up to six weeks ago. No signs of cardiac disease could be discovered.

UNUSUAL SEQUELÆ OF TYPHOID FEVER.

Dr. A. R. Parsons showed a patient with enormous dilatation of the veins on the abdominal wall. The man had typhoid in 1893. The onset of very acute pain in the right iliac fossa had caused so much suspicion of perforation that laparotomy was performed. No perforation was found, and the patient made a comparatively uneventful recovery. Two years later the patient showed signs of obstruction in the two iliac veins, or perhaps in the inferior vena cava. No inconvenience was experienced by the patient.

Mr. R. Atkinson Stoney showed a patient, æt. 41, in a very similar condition. When in South Africa in 1901 he had enteric fever. Was in hospital for three months, in bed the whole time, with two relapses. No bleeding from the bowels at any time. In convalescent camp for one month, then during voyage home noticed swelling of both legs for the first time, most marked in the right leg, which was said to have been 5½ inches larger than normal. No enlargement of veins of legs noticed at this time, but veins on front of abdomen were noticed to be enlarging. Was in a convalescent home in England for two months, and was then discharged from the army. Has since been in the Canadian Police. Veins in legs became enlarged while in that force in 1904; enlarged veins in thigh gave trouble when riding. Varicose ulcers first formed on legs in 1910, healed and broke down twice since then. At present there was a very large tortuous vein running up on each side of the abdomen from below the middle of Poupart's ligaments to the corresponding axillæ, the blood flow free in either direction. There was another large tortuous vein running on each side of the middle line from the same origin to the front of the sternum. The femoral vein could be felt as a hard cord in each leg up to Poupart's ligament. The condition was probably due to occlusion of iliac veins and inferior vena cava.

Sir John Moore related a case of his which resembled these cases, but the dilatation of the superficial abdominal veins was unilateral.

The **President** and **Drs. Moorhead** and **Law** discussed the condition. There was a general feeling that thrombosis of the femoral veins was a more frequent sequel of typhoid than statistics led one to believe.

ENDOCARDITIS LENTA.

Dr. Gillman Moorhead read a paper on this subject, and showed the organs from a patient who had succumbed to the disease. The condition had supervened on a chronic endocarditis. The aortic valves became infected after the mitral valves. The spleen was enlarged, and there was moderate nephritis. Streptococcus viridans had been cultivated during life from the blood, and recovered also *post mortem* from the valves.

The **President** thanked Dr. Moorhead for his contribution, as he considered it a distinct acquisition to know that this type of endocarditis had a definite coccus as its recognised cause. A point which came into his mind was that when a case came into hospital with an old cardiac lesion one was prone to assume that the patient was tired from the effects of his old disease, whereas he might have a new endocarditis.

Sir John Moore and **Drs. Nesbitt, Crofton,** and **O'Kelly** discussed the condition.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.

Meeting held Wednesday, December 17th, 1913.

Mr. Charles Heath in the Chair.

Mr. Heath read notes on a case of aural suppuration and rapid metaplasia of the covering epithelium of the antral lining, and showed microscopical slides. The attack of otitis media followed a cold in the head. The infection was a diphtheroid bacillus (Hoffmann's). There were no squames in the discharge at the first examination. Autogenous vaccines were given. Two days later there were a few squames in the discharge. The patient was confined to bed and warmth applied to the ear. At the end of a fortnight squames were found in great abundance in the discharge. The hearing had meanwhile considerably deteriorated, due (in his opinion) to swelling of attic and tympanic mucous membrane. After a consultation with Dr. Jakins, it was decided to operate by the conservative method in order to arrest disease and prevent deafness. At the operation the pericranium and bone were found to be vascular, and there was pus in the antrum. The lining of the cavity was greatly thickened and the attic was obstructed by swollen mucous membrane. Dr. Wingrave's report upon the structure of the antral lining was as follows:—"The tissue is granulomatous of a simple type, covered with a distinctly thickened layer of stratified epithelium, whose upper layers are distinctly squamous. Plasma cells are numerous, mixed with lymphocytes and rudimentary blood-vessels. There are no 'giant' and no 'syncytial' cells. The epithelium well illustrates metaplastic changes from the simple flattened or cubical type which normally lines the cavity." Mr. Heath pointed out that such clear evidence of rapid metaplasia is rarely forthcoming, but the history of perfect hearing in both ears up to the onset of otitis media cannot in this instance be questioned. The case affords definite proof of the metaplastic change which Dr. Wingrave was the first to describe and of the rapidity with which it may occur. Mr. Heath wished to emphasise the need of early surgical assistance in such cases with the object of preventing deafness, and for this purpose had brought the matter before the Society. Only four weeks had elapsed since the operation, yet the perforation had healed and the hearing was now equal on the two sides.

Mr. Heath also showed several preparations of healthy recent temporal bones, which illustrated some of the causes of perpetuation of discharge after an attack of otitis media: (1) the inner tympanic wall, showing an unusual sinus beneath the promontory; (2) the inner wall of the tympanum, showing three unusual sinuses, one of which is sub-Eustachian; (3) a bone showing the external semi-circular canal projecting into the aditus; (4) a safe antrum with smooth walls and a lining of mucous membrane; (5) a bone showing the route of antral drainage through Shrapnell's membrane; (6) large bone cells in the mastoid process which are separated from the mastoid antrum by muco-periosteum only; (7) a temporal bone showing corpuscular bodies in the antrum, also that drainage escaping through Shrapnell's membrane does not pass through the tympanum at all; (8) the inner wall of the tympanum, showing fibrous fixation of the stapes resulting from long past disease; (9) bone showing the sclerosing effect of chronic aural suppuration.

Mr. Adair-Dighton, Dr. Frederick Spicer, and Dr. Percy Jakins each congratulated Mr. Heath on the excellent preparation of these bones, and pointed out that their educational value was very great, and that they hoped Mr. Heath would exhibit them again on some future occasion.

Dr. Walker Wood read notes of a case which illustrates the value of the naso-pharyngoscope (Holmes's) in the diagnosis of naso-pharyngeal and aural conditions. Miss H., æt. 50, complained of tinnitus and deafness in the left ear and a feeling of a foreign body in the throat. Both ears showed signs of chronic middle-ear catarrh. Ordinary post-rhinoscopic examination was impossible. Naso-pharyngoscopic examination with Holmes's instrument showed the right side to be normal, and on the left side a cyst was found occupying Rosenmüller's fossa, a coloured drawing and microscopic specimen of which were shown. The cyst was removed through Yankhauer's speculum. This was followed by complete relief of abnormal pharyngeal sensation and tinnitus. The hearing also improved. The case had been under treatment for tinnitus in France and Switzerland without the cause being discovered. Dr. Wood expressed the opinion that the cyst in this case was due to cystic degeneration of an adenoid mass in the lateral recess of the pharynx (Rosenmüller's fossa). Microscopic appearances endorsed this view. He found that cysts in this region were very rare, and had been unable to find any recorded cases. He had examined the naso-pharynx in 1,850 cases. He also referred to the difficulty in many cases of post-rhinoscopic examination. By Holmes's method it was always possible to make a painless and thorough examination. He cited several other cases in his own experience and those of others at home and in America.

Dr. Frederick Spicer congratulated Dr. Wood on his interesting and instructive case, and expressed his opinion that this method of examining the naso-pharynx had not been sufficiently appreciated.

Mr. Charles Heath said that Dr. Wood had examined a great number of his patients by this method, and the information thus obtained was occasionally of great importance.

Dr. Percy Jakins and Dr. H. D. McCulloch also took part in the discussion, and Dr. Walker Wood replied.

LIVERPOOL MEDICAL INSTITUTION.

The Second Pathological Meeting of the Session was held on Thursday, December 11th, 1913.

Dr. Lloyd Roberts in the Chair.

The following specimens were shown and described:—

Dr. Leith Murray showed three cases (two of which were under the care of the late Dr. A. Wallace) of adenomyoma of the posterior vaginal wall immediately below, but distinct from, the cervix. In two of these the growth, histologically simple and identical with a uterine adenomyoma, but burrowed through the recto-vaginal septum and infiltrated the wall of the rectum. Dr. Murray discussed the ætiology.

Dr. N. Raw: Carcinoma of stomach involving œsophagus.

Mr. Litler Jones: (1) Hydronephrotic kidney with papilloma of the ureter; (2) sequestrum of lower jaw.

Mr. Litler Jones and Dr. Buchanan: Human "hair ball."

Mr. G. P. Newbolt and Dr. Murray Cairns: Human "hair ball" weighing 4½ lb., which had been successfully removed by Mr. Newbolt from the stomach of a girl, æt. 16.

Mr. G. P. Newbolt: (1) Human "hair ball" weighing 9 oz., which he had successfully removed in the year 1908. In this case a bismuth X-ray photograph clearly showed the outline of the hair ball; (2) round-celled sarcoma of the bladder wall; (3) carcinoma of the kidney.

Mr. R. C. Dun: (1) Lymphadenoma; (2) vermiform appendix containing thread worms.

Professor E. Glynn: (1) Two human "hair balls"; (2) "hair balls" from animals.

Dr. W. B. Warrington: Tumour in the right posterior fossa of the cerebellum. It was the size of a small walnut, growing between the fifth and seventh nerves. During life the only focal symptom was right corneal areflexia. The posterior fossa was explored on the right side, but owing to the interior and anterior site of the tumour its presence was not detected at the operation. Histologically the tumour was composed of innocent fibrous tissue.

Professor J. W. W. Stephens and Mr. F. Jeans: Chinese lady's foot. Surgically it is in a condition of pes cavus, whilst pathologically the deformity is mainly produced by a change in the os calcis, which is L-shaped, the patient walking on the insertion of the tendo Achillis.

Professor J. W. W. Stephens: (1) Bilharzia of bladder and intestine; (2) guinea worm; (3) colour photographs from lip of tsetse fly; (4) redshank trapped by cockle; (5) fossil tsetse fly; (6) bot parasite on tapeworm.

Dr. Blair Bell: Sarcoma of the ovary.

The specimens were discussed by Mr. F. Paul, Dr. Thurstan Holland, Mr. G. P. Newbolt, and Mr. Litler Jones.

Professor J. W. W. Stephens read a paper on

THE RELATION OF BLACKWATER FEVER TO MALARIA.

Dr. Prout discussed the paper and said that he supported Professor Stephens in his view as to the relationship between malaria and blackwater fever. The more he had seen of this disease in the Tropics—and his experience was very considerable—the more he was impressed from a clinical point of view with its relationship to malaria. He thought some of the figures cited by Dr. Stephens very convincing, and he considered that additional confirmatory evidence might be cited in the results of the prophylactic use of quinine. Where this had been systematically done, it had been found that blackwater fever had diminished as well as malaria.

Dr. Lloyd Roberts, Dr. Bradley Hughes, Dr. Stallybras and Dr. Harcourt also spoke.

Professor Stephens replied.

SPECIAL REPORTS.

POLICY OF THE PLUMBERS' COMPANY.

In the Hall of the Armourers' and Braziers' Company, the Livery dinner of the Plumbers' Company was recently held. The Master, Mr. W. D. Caröe, M.A., presided, and there were present many guests, including the Lord Mayor (Sir Vansittart Bowater), the Master of the Armourers' Company (Dr. G. Newton Pitt), Sir John Anderson, G.C.M.G. (Colonial Office), Dr. F. J. Waldo, J.P. (Warden), Sir Shirley F. Murphy, Dr. A. E. Newsholme, C.B. (Medical Officer, Local Government Board), Mr. Frederick M. Simpson, F.R.I.B.A., Dr. Herbert Williams (M.O.H., Port of London), and Dr. S. Squire Sprigge.

Sir Shirley F. Murphy said that the Plumbers' Company, as they were aware, had done important work in improving the standard of plumbing in this country. It always hoped by increased powers to do still more, for there was no want of will on the part of the Company. (Hear, hear.) Turning to the Corporation, he said that recently he was looking through some old records, and he realised, as never before, what that body had done, not only for the citizens, but for the whole of England. He was sure that everyone would say that the Lord Mayor and the Corporation had always recognised their responsibility in regard to public health.

Proposing the toast of "Public Health and the Plumbers' Company," the Lord Mayor said he thought the Corporation and the Plumbers' Company went together, for both were doing all they possibly could for the public health. There was no doubt about it, that the Company was doing a real good service to the City, and not only the City, but to the entire Empire, because if we could not have good plumbers we could not have good sanitary houses. No man had any right to call himself a plumber and act as a plumber unless he were really qualified and had gone through some examination to fit himself for that position. It must be an enormous boon that there should be such a company that would labour as the Plumbers' Company had done for those engaged in the industry. (Hear, hear.)

The Chairman, in responding, said that it was the aim of the Company to improve the public health through the improvement of plumbing work. While their charter, which was granted by King Edward III., was undoubtedly intended in a secondary way for the protection of the plumber, it was intended primarily for the protection of the public health, so their association with public health went back a very long way. There was no doubt that the old plumbers were extraordinarily skilful people so far as they went. Recently he had the privilege of cutting off a piece of pipe from one of the old abbeys, that at Furness, and no modern plumber had been able to tell him how the pipe was made. They admitted that they could not make such a pipe to-day. He had no doubt it was because the plumbing work in the Middle Ages was so well done that our buildings had lasted so long. When they came to the Victorian era, he was afraid the work of the plumber went to smash. The fact was that in those days houses commenced to spread to the suburbs, the jerry-builder came to the fore, and the jerry-plumber also came to the fore.

At a congress held at Liverpool the Plumbers' Company were asked to put their hands to the plough and see whether they could alter matters somewhat. They asked for registration as a method of improving the status of their trade, and always associated with it examinations, practical tests, and so on, because registration by itself was useless. They introduced a Bill in the House of Commons on those lines and spent a vast amount of money, but owing to the Government dissolving, the Bill went to the wall. A good deal of money had been spent for nothing. Finally they came to the conclusion that they must proceed on other lines. In New Zealand, which was one of the leading colonies, the Plumbers' Registration Bill had been adopted, and there every plumber had to be registered on the lines advocated in the Bill promoted by the Plumbers' Company. By the registration system the matter had been handed over, as far as possible, to the plumbers themselves, which was a democratic advance, and he was bound to say that the master plumbers and the operatives had taken a great deal of interest in the suggestion.

The Company had always recognised that associated with the plumber and his interests were the public, and they had always working with them representatives of corporations, water boards, and health authorities. They had met with a great deal of opposition. Ironmongers and people of that kind who called themselves plumbers seemed to think that they would be snuffed out if there was registration. Then there had been a curious form of opposition, mostly from Radical Members of Parliament, who feared that an aristocracy of trade was being created, but nothing more absurd than that idea could have been conceived. Referring to the system of marking plumbers' work by the men's registered numbers and the marks of the employers, the Chairman said that it entirely dissociated the registered man from the ordinary man who had no association with the scheme. He was glad to think that they had followed the lines of some of the other City Companies. Recently the Goldsmiths' Company had been doing some plumbing work and had adopted the mark system. The City of London would be doing a great deal to further the objects of the Plumbers' Company if they would pass to their officials the order to mark plumbing work done for the City. If Water Boards' engineers, architects, and Corporation engineers would take the matter up, the Company's work in that direction would be done; but, of course, if they did not get that support, they might retire from the business. They had received a great deal of support, but the point that had given him satisfaction was the support received from the men themselves. The men had always loyally supported the work the Company had done, and they recognised that it was to their advantage. (Applause.) It cost a little more, but he felt sure that builders would find it to their advantage if they could say to their tenants that the whole of their houses had been marked by the system of the Plumbers' Company. (Applause.)

Dr. G. Newton Pitt (Master of the Armourers and Brasiers' Company) also responded. He said that perhaps more than the general public the medical profession appreciated the magnificent work that was being done by the Company.

Ald. Sir T. Vezey Strong, proposing the toast of "The Guests," said that unless they could show to the skilful operatives that there was some real trade advantage in belonging to the mark movement they would be slow to recognise on the abstract standard of greater efficiency the inducement to pay even a small subscription. They all believed that it was of the first importance to protect the health and prolong the lives of the public.

Sir B. A. Whitelegge also acknowledged the toast, remarking that the Plumbers' Company, like so many of the City Guilds, had taken a wide view of their responsibilities and opportunities. The idea of associating the work of the individual by a mark seemed to him a most delightful one. Some of them worked in another branch of public health, which consisted of the examination of sanitary inspectors, and in that he had had the assistance of their excellent clerk, Mr. W. R. E. Coles, and had good reason for admiring his untiring efforts in that direction. (Hear, hear.)

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Dec. 27th, 1913.

INTRAVENOUS INJECTIONS.

From day to day, says Dr. Noel Fiessinger, the method of introducing medicated solutions into the economy through the veins increases in popularity. Numerous drugs are more active when administered in this way, while others cannot be injected into the muscles except at the price of intolerable pain, whereas intravenous injection is indolent. The instruments needed for this method are few and simple —a bandage or a rubber tube and an hæmostatic forceps to fix the ligature above the elbow; tincture of iodine; a glass syringe (2 c.c. or 20 c.c.); a rather short and thick needle.

The patient is lying down, the right arm extended (the right arm is chosen as the veins are more visible than in the left). The ligature is placed on the arm, but not too tightly, and while the veins are being engorged, the syringe with its needle is sterilised by boiling, and a little tincture of iodine painted over the bend of the elbow. The operator must not forget to thoroughly wash his hands before proceeding to manipulate.

The solutions to be injected are varied—electrargol (10 to 20 c.c.), collargol (5 to 20 c.c.):—

Collargol, 1 gr.
Water (sterilised), 100 gr.

Cyanide of mercury (1 to 2 c.c.). This salt of mercury is specially employed for intravenous injections; intramuscular injections are too painful.

Oxycyanide of mercury, 0.01.
Distilled water, 2 c.c.

For one ampoule.

All the varieties of serums can be injected into the veins—those for diphtheria, tetanus, snake bite, etc. The serum must be fresh, and at least 20 c.c. should be injected at a time. Neo-salvarsan is injected according to the method of Ravant. Thirty centig. are dissolved in 20 c.c. of distilled water, freshly sterilised. The solution is drawn up into the syringe after having placed between the needle and the body of the syringe a small glass tube containing a plug of gauze to prevent the entrance of undissolved particles. Everything now being ready, the left hand of the operator embraces the middle of the forearm of the patient; the thumb is placed on the vein about to be punctured to prevent, by gentle pressure, the skin from gliding and the vein from escaping from the pressure of the needle. The air is expelled from the syringe held in the right hand. The veins generally chosen are the cephalic and the basilic. The direction given to the syringe and needle is that of the vein, with a very slight obliquity, the point being directed towards the root of the limb with the bevelled part facing the operator. The skin is pierced by gentle pressure and very obliquely. When this is done, the needle, taking the direction of the vein, enters it laterally or superficially. That the needle has penetrated into the vein is proved by the sudden disappearance of all resistance and the arrival of a drop of blood into the syringe. The syringe is held firmly in the hand, the left hand removes the ligature, and the liquid is slowly injected. When terminated, the needle is withdrawn rapidly, and a little tincture of iodine is applied to the wound; no other dressing.

Some operators insert the needle first and then adapt the syringe, but this method is more delicate and requires some habit.

Several little accidents may occur, mainly due to nervousness on the part of the operator. The liquid may be injected into the cellular tissue by a sudden movement of the patient. The fact will be announced by the patient himself, who will complain of pain, and to the operator by the presence of a swelling. In such case the needle should be withdrawn. No attempt should be made to find the vein again. Moist dressing will be applied to the arm, which is to be immobilised. The vein may be transfixed. The cause is usually due to the needle, which is too fine. The operation should be resumed on another vein.

The vein is invisible. It frequently occurs, especially in women, that the vein cannot be seen. Dissection of the vein is the only way out of the difficulty, or some other way of administration must be chosen.

Air in the vein is an accident of but little consequence, yet precautions should be taken against it. Phlebitis and hæmatome are possible accidents very simple in their treatment—wet compresses, bandage.

Certain general accidents, however, may give rise to some apprehension. Rigor with high temperature: The patient should keep his bed for 24 hours and be put on simple diet. This reaction, according to Dr. Fiessinger, is due to a too sudden destruction of the leucocytes and the setting free of proteolytic ferments.

The advantages of the intravenous method are painlessness of the injection and rapid and direct therapeutic action. Intravenous injections are much less painful than intramuscular injections, and those patients who have been treated by both methods prefer by far the former.

Every practitioner should, from this day, accustom himself to this method of modern therapeutics. After a few trials he will become an expert and recognise all its advantages.

GERMANY.

Berlin, Dec. 27th, 1913.

At the Medizinische Gesellschaft, Hr. Bönniger discussed the

Treatment of Pulmonary Tuberculosis by Artificial Pneumothorax.

The patient on whom the treatment had been carried out was a young woman, æt. 19, who had suffered from serious unilateral tuberculosis of the left lung. She first came under treatment in October, 1911. There had been high fever for weeks, hæmoptysis, copious expectoration, which contained masses of tubercle bacilli. The pneumothorax was now made, and after a year and a half the result was very good. The fever ceased, the patient gained 25 lb. in weight, and at present had no trouble beyond a slight stitch in the left side, no cough, no expectoration, and she was quite able to do her work. But the good result alone was not what made the case so much worth bringing forward, but rather what was shown by the X-rays. Before the operation there was every sign of diffuse tuberculous deposit throughout nearly the whole of the left lung. The second skiagraph showed a pneumothorax at the apex and adhesions at the diaphragm. The third showed slight diminution of the left lung field, but the patchy darkening was almost gone, the left side was a little clearer than the right. On deep inspiration it brightened up less than it did on the opposite side. He had never seen such a result from any kind of treatment during the whole of the ten years he had been working with the X-rays. Such a case spoke not only for the extraordinary effect of treatment by pneumothorax, not in cavernous tuberculosis alone, but it served as a standard as to what could be reached in the treatment of tuberculosis. Here he had to thank Friedmann's remedy. And here he must add that Herr Immelmann would soon be able to show them something similar.

Hr. Blumberg showed a

Large Tumour of the Urethra Cured by Radiation with Mesothorium.

He begged to be allowed to show a patient who had suffered from carcinoma urethræ who had been sent to him from the Schöneberg Hospital as inoperable. The patient was in the hospital from July 25th to September 15th, when she was transferred to his clinic. The patient was 78 years of age. From the commencement of the year the urine had been occasionally bloody, but it soon became so all the time. The condition on admission was as follows:—There was a large, hard, knobby tumour in the anterior wall of the urethra. Commencing about 2 ctm. above the external orifice, it reached upward to the portio vaginalis. At its distal end the growth was nearly two finger-breadths wide. The parts were very inaccessible owing to an ankylosed hip-joint, and X-ray treatment was out of the question. It was thought wise not to give a general anæsthetic. Irridiation with mesothorium caused disappearance of the tumour in a comparatively short time. After three weeks, when about 4,000 milligram hours had been applied, the tumour was distinctly smaller, and in another week it could no longer be felt. A total, therefore, of 6,000 milligram hours had been applied. To make sure, however, another 1,000 were given. The last application was made four weeks ago, and palpation still yielded a negative result. She had been examined by numerous colleagues, who were satisfied that the tumour had disappeared. The speaker was of opinion that the *technique* of application contributed perhaps to the rapid change that had been effected. He had not made use of a lead filter, which might lead to severe burning by secondary rays, but a gold filter, and after that one of brass, which he believed he could specially recommend.

AUSTRIA.

Vienna, Dec. 27th, 1913.

Pavor Nocturnus: Its Treatment by Suggestion.

At the recent meeting of the K.k. Gesellschaft der Aerzte in Vienna, Dr. Fr. Hamburger made a communication on the subject of pavor nocturnus and its equivalents (oneirogenic conditions). A distinction was made between the symptomatic and idiopathic forms of pavor nocturnus. The symptomatic included those forms of nocturnal outcry which are so frequently met with in every possible variety of the febrile disorders of children. On the other hand, idiopathic pavor is nearly always attributable to some agitating experience of daily life. A typical feature of its occurrence is that such attacks repeat themselves for a number of nights, sometimes for even a number of weeks, in continued succession. Various other disturbances of sleep often form an equivalent of pavor nocturnus. Thus Dr. Hamburger had observed a case of frequent coughing during sleep. Other examples are furnished by paroxysmal attatcks of vomiting, of abdominal pain, of fits of laughter, etc. He now proposed that all such disturbances of sleep should be regarded as oneirogenic ("oneiros" = dream). It is of the greatest practical importance in this connection that we should recognise the fact that we are in possession of a therapeutic agent which has the most effective influence on all oneirogenic conditions. This consists purely of the application of "suggestion" during the time of waking: we prescribe five or ten drops of tinctura amara or chinæ, to be taken before going to sleep. And here it is of the utmost importance that we always, in such circumstances, promise the desired result with the most absolute confidence. It is also important that the taking of the medicine should be the last act of the patient before going to sleep. The previously ordained times and succession of evening arrangements and habits should also be altered—including those of getting to bed, and the stated hour for going to sleep. Thus, it should be arranged that children who had been in the habit of having their bath before the evening meal, should now have it after, and *vice versa*. It is also expedient that children should have some new diet prescribed for them for the evening; and it is of the utmost importance that the drops should be administered after evening prayers, which is usually the last procedure before going to bed. No further admonition of any kind whatsoever should be given to the child after the administration of the drops. With this form of therapeutic manipulation we are enabled to effect the cure of pavor nocturnus; and the desired effect depends on the individual physician, who must prescribe it with all the necessary earnestness, the adequate impressiveness, and confident establishment of faith in the effectiveness of its administration to the child, who should be persuaded into an unquestioning belief in its efficacy.

Estimation of Hydrochloric Acid of Gastric Juice without Use of Stomach-pump.

Dr. G. Schwarz made a communication on the subject of testing for hydrochloric acid without using the stomach-pump, in which he pointed out that Spath had, in 1887, introduced a method by means of which (in cases in which the introduction of the stomach-pump was undesirable, or the opposition of the patient made it impossible) the investigation could be carried out by getting the patient to swallow, after the test breakfast, a silk thread, stained with Congo-red, to which a little globe of lead was attached. Friedrich has recently adopted this method of procedure with his "gastrognost." But as the extraction of the leaden globe is accompanied with difficulty, and with sensations of extreme pain to the patient, this formerly celebrated procedure could not become of universal adoption. On this account, Dr. Schwarz has modified the procedure by substitution for the solid globe of metal of a soluble gelatine capsule filled with a heavy powder (pulverised metallic bismuth, barium sulphate, cerium oxide, etc.) The capsule dissolves in the gastric juice, and the unloaded Congo thread, stained more or less according to the degree of acidity, withdrawn without any unpleasant sensations whatever to the patient. If the thread has retained its red colour there is no hydrochloric acid present. In such case, Röntgen-ray illumination should be utilised for the purpose of ascertaining whether the capsule had actually reached the stomach, or had been arrested in its descent by an œsophageal constriction or an hour-glass contraction of the upper part of the stomach.

Dr. E. Schulz held that the procedure thus introduced was not reliable. We could not decide whether the capsule had reached the stomach so far as to be placed in contact with the gastric contents. Whatever experimental value this method may have, it, as in case of other proposed substitutes, can never attain to the reliability of the stomach-pump, far less supplant it. It could also be observed when the gastrognost and the tube had been used on the same individual, that the use of the latter was much less unpleasant to the patient than the swallowing of a string with its attached capsule which it took several minutes to swallow in most cases, after which the string had to be left hanging out of the mouth for half an hour. If, however, we want to dispense with the use of the stomach tube, we can have recourse to the simple, convenient and relatively reliable so-called sodium test, which was introduced by Field, and afterwards modified by Ridner. This consists of getting the person to be experimented on to swallow, after the test-breakfast, a solution of soda (2 grammes in 50 of water), while the ear is applied over the gastric region. When free hydrochloric acid is present, the characteristic sound of effervescence is heard, due to elimination of free carbonic acid gas. In cases of absence or of abnormally loud report of effervescence, we can also conclude the respective absence or relative increase of free hydrochloric acid. This procedure is so very simple that it can be carried out even in business hours and at intervals of two or three hours after the midday meal. It had given the speaker very important directive indications towards therapeutic procedure. He would, however, warn his hearers against regarding any of these "substitution" methods as reliably conclusive with regard to the exact proportion of free hydrochloric acid present.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

GLASGOW.

At the recent meeting of the Glasgow Branch of the Research Defence Society, among other letters of apology for absence read was one from the Right Hon. A. J. Balfour, in which he said: "I am much concerned to hear that, on alleged humanitarian grounds, an effort is being made to hamper research in the Glasgow hospitals by cutting off public subscriptions, on which they depend. I do not in the least impugn the motives of those who are responsible for this policy; I do not doubt either their sincerity or their kindness of heart. But I am firmly convinced that nothing will so minister to the diminution of physical suffering, both among men and animals, as that profounder knowledge of pathology which can only be obtained by patient, long continued, and, alas! costly investigations, such as those which are now being carried on at the Cancer Hospital and elsewhere."

Glasgow Burgh Insurance Committee have now come to a decision as to the allocation among the panel practitioners of the undistributed patients. These are to be allocated equally among those practitioners whose lists are under 1,500, but so as not to raise any list above that number. Any practitioner may, however, decline to have his list augmented by the allocation.

At the annual Christmas meeting in connection with the Western Infirmary, the chairman, Sir Matthew Arthur, Bart., congratulated Dr. Mackintosh on having completed 21 years as medical superintendent. During that period, while the daily average number of occupied beds had grown by about a half, and the number of nurses had increased from under 100 to over 200; the in-patients treated during the year had much more than doubled, having grown from 4,083 to 9,391. That meant, of course, a shorter period of residence, and pointed to greater efficiency.

A very important development in connection with the work of the Infirmary had been the Clinical Laboratory, which so greatly assisted in the diagnosis and treatment of disease. Lady Arthur afterwards presented the nurses' prizes, including the "Florence Nightingale" medal, won by Nurse Margaret Wallace, who also gained the first prizes in both surgical nursing and medical nursing at the examination held in October. Sir George Beatson spoke, and Sir Hector Cameron, who followed, said his memory of nursing in Glasgow went back to the early 'sixties, and at that time the women who nursed were elderly women, for the most part impecunious widows, who took up nursing for want of anything better to do. In regard to education and feeling, they were very much of the same class as present-day charwomen, though there were certainly exceptions who were excellent women. The profession of nursing had developed into a very important one. In a matter of forty years it had taken a very high position in the community, and that really meant that it increased the responsibility of every one of those who entered it. What really constituted nursing was personal character, and they could not have that character in too highly developed a form.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE QUESTION OF REFORM OF THE B.M.A.

To the Editor of The Medical Press and Circular

Sir,—Dr. S. J. Ross agrees with me that the present situation in the B.M.A. is due to the apathy of the majority of members. But does he believe that this apathy is to be overcome by raising the subscription? Will it not rather drive out a large section of the indifferent and discontented? The first thing called for is financial overhaul and reform; the second, the recasting of the administration into a form in which it can act with vigour as the elected and authorised guardian and promotor of the interests of a united profession. In the sphere of finance the *Journal* needs first attention. It is three times too big in every department, but in cutting it down it would not be necessary, as Dr. Ross supposes, to dispense with any essential part. Not as many as 5 per cent. of the scientific papers and lectures of any kind deserve full or verbatim report, They could nearly all be condensed to a quarter with advantage. There are too many editorials, and those too long; whilst the Notes of the Week are each long enough for a leader. Whole sections of uncalled for matter, pages of *Nova et Vetera*, for example, are often put in, whilst the majority of new books which deserve no more than a brief notice get lengthy reviews. The Epitome of Literature is of doubtful value; all that is needed is the briefest possible record of real advance in research and of established progress in diagnosis and treatment. The sum paid to editorial contributors might be cut down one-half; the outlay on the production of the body of the paper might be equally reduced. A circulation of 25,000 a week will always command advertisers. If the charges were increased some might be lost, but income would not be lowered to any important extent. The income from advertisements now amounts to £30,000 a year. A property like the *British Medical Journal*, managed throughout on real business lines, ought to produce an annual profit of £5,000 to £10,000.

I am, Sir, yours truly,
An Obscure Member.

Christmas, 1913.

FAITH HEALING AT UNIVERSITY COLLEGE.

To the Editor of The Medical Press and Circular.

Sir,—It is evident that Dr. Maurice Craig is not in the least to blame for the deplorable fiasco in the attempt to set up a Psycho-Medical Clinic at University College, and that he is, if possible, still less responsible for the harm that has been caused by the reports of the meeting at which inauguration of the Clinic was attempted. The prominence which was given to the report in the *Times* and all the leading London papers led to its reproduction throughout the entire British Press. The report will certainly appear also in due course in all the colonial papers. The meeting took place in University College—an institution representative of everything that is advanced in science and opposed to vulgar credulity and superstition, and the utterances put forth have been naturally accepted by the public as sanctioned by the highest medical authority. The persons primarily responsible for this mischief are, of course, the organisers of the meeting. It is remarkable that no explanation of the procedure and of the selection of a chairman has been forthcoming. In the meantime, the number of miserable dupes of the faith-healing fraternities has been increased, and the operations of the clever quacks who are out only to plunder have been greatly facilitated. Pseudo-religious fanatics of the Christian Science type, and faith-healers who glory in their total ignorance of science, and who sincerely believe in their miraculous powers, have all received encouragement, whilst the cruel, cynical and fraudulent quacks who amass wealth by preying upon hypochondriacs and *malades imaginaires* have gained a real, albeit gratuitous advertisement. I can, as you are aware, support by personal knowledge your statement that a large number of the victims of quackery in this, as in every other line, "are led on to perfectly preventable death whilst relying upon useless methods in cases easily amenable to scientific treatment."

I am, Sir, yours truly,
Scrutator.

December 27th, 1913.

INCOME TAX DEMANDS.

To the Editor of The Medical Press and Circular.

Sir,—The collectors of taxes are now making their annual distribution of demand notes for the current year, the tax for which is payable on or before January 1st next. Before paying the amount demanded your readers should be careful to ascertain that the amount is correct, and that they have been allowed all the deductions to which they are entitled. Particularly they should see that they are not paying inhabited house duty and land tax, for which they are not liable, as it is generally impossible to obtain any repayment of these duties. Repayment of income tax overpaid can now be claimed for the three years ended April 5th last; this applies, of course, more especially to income derived from investments, house property and annuities, and also claims in respect of life assurance premiums and the allowances for children under 16.

We are, Sir, yours truly,
Tax Adjustment Agency.

London, W.
December 29th, 1913.

THE NATIONAL MEDICAL GUILD.

To the Editor of The Medical Press and Circular.

Sir,—In your special report of the meeting held on the 19th inst. a brief summary of some remarks I made occurs under the name of Tompkins, which my best friends would not recognise, as I am Harding H. Tomkins. I wonder if you could spare room to correct the name?

Now that the British Medical Association has not only an Insurance Act Committee to supervise all matters affecting the profession (particularly panel doctors), but an energetic non-panel committee, I, as a non-panel man, cannot see why it should not be able to unite all sections of the profession by efficiently looking after the interests of all, just as well as a large business house can efficiently work several departments. Now that arrangements are on foot for four organising secretaries, "it is up to" the varying sections of the profession to acquaint the Association of their desires and any constructive policy, and by a strong backing enable the Association to act for them, instead of by destructive criticism paralysing all action. Then let every practitioner (whatever else he belongs to) join the Association, and as a united profession work for the commonweal of public and profession alike. So convinced am I of the necessity of a united profession, that I am Secretary of the Local Medical Committee of Essex, and advocate the Association co-ordinating all the Local Medical Committees, for however misguided the panel doctors were in their action, we non-panel should help to work for the good of the whole profession and conform to our original policy of making the Act such as the whole profession could accept. That was the policy I kept my pledge for and what I consistently work for.

I am, Sir, yours truly,
Harding H. Tomkins,
Chairman S.W. Essex Div. B.M.A.

Leyton, Essex.
December 26th, 1913.

THE DISCOVERY OF THE LIFE-CYCLE OF THE ORGANISM OF SYPHILIS.

To the Editor of The Medical Press and Circular.

Sir,—My attention has been drawn to the leading article on "The Discovery of the Life-cycle of the Organism of Syphilis" which appeared in the Medical Press and Circular on December 17th last, and which contained frequently my name with those of my brothers. This article reopens an old controversy about the priority of description of a complex parasite believed to cause syphilis in human beings, the type of which was described in the "Proceedings of the Royal Society" some two years ago. I beg that you will inform your readers that one aspect of this question was published by me in the medical papers a year ago—a point which your article omits to mention. Personally, I would rather not reopen the matter at the present time.

After all, the important thing is to prove experimentally, according to Koch's postulates, that the "bodies" as mentioned in your article are pathogenic parasites at all.

I am, Sir, yours truly,
E. H. Ross.

December 29th, 1913.

OBITUARY.

COL. J. H. NEWMAN, M.D., INDIAN MEDICAL SERVICE.

Col. J. H. Newman, who recently died at his residence, Coolatta, Killinardrish, co. Cork, was a distinguished officer of the Indian Medical Service. He studied medicine in the Queen's College, Cork, and took the degrees in Medicine and Surgery of the Queen's University in 1865. In 1867 he entered the Indian Medical Service, taking part in the Abyssinian campaign of 1868. Later on, in 1878, he was through the Afghan War, and had the medals for both these campaigns. The greater part of his service was passed in Rajputana. He was Civil Surgeon of Ajmere from 1879 to 1892, though occasionally filling temporary posts in higher offices elsewhere. In 1895 he became Principal Medical Officer, and in this year was appointed Inspector-General of Hospitals in Bengal, and also Administrative Medical Officer and Sanitary Commissioner for the Central Provinces. Before his retirement in 1900 he held the same position in the Punjaub. Colonel Newman had a wide reputation in the profession and was beloved by his patients. With many accomplishments, a keen, all-round sportsman, a reliable friend in difficulty or emergency, "Jack" Newman was popular and beloved wherever he went.

DR. J. H. BROWN, OF SHEFFIELD.

We regret to record the death of Dr. John Henry Brown, which took place at his residence, 2 Edgehill Road, Sheffield, on the 12th inst., aged 54. The deceased, who was born at Selby, spent his early life at Whitby. He was educated at Edinburgh University, becoming M.B., C.M. in 1883, and taking the M.D. three years later. After having filled the offices of House Surgeon at Dewsbury Infirmary and Manchester Royal Infirmary, he came to Sheffield about 23 years ago, where he lived for many years in Burngreave Road, and there built up a large general practice, but illness some months ago necessitated his removal to Nether Edge. Dr. Brown was a Freemason. He was Surgeon to the Midland Railway Company in Sheffield district, and took a deep interest in ambulance work among railway workers. He filled the position of President of the Obstetrical Section of the British Medical Association on the occasion of the 1908 visit to Sheffield. Dr. Brown leaves a widow and three children, for whom the deepest sympathy is felt in their sad loss.

REVIEWS OF BOOKS.

BLOOD-PRESSURE. (*a*)

This volume deals with a subject which, as all readers know, has been very much "in the air" of recent years, and is likely to remain so for a good many years to come. The author has, accordingly, done good service to his professional brethren in his present effort "to present in easily accessible form the pith of medical literature bearing on blood-pressure studies in their relation to medicine." And in this garnering process he has not confined himself to the cardiovascular and renal conditions which long limited the purview of investigators in this department of clinical knowledge, but included the most recent results of research in regard to many diseases in which the most careful clinical observation has gone to prove the sterling value of the information supplied by the sphygmomanometer. It is not, of course, an original work, but represents chiefly a skimming of the cream of the medical literature which has appeared on this important subject during the last seven or eight years. The skimming process has been carefully and conscientiously carried out, and every sane reader knows that in such a work it is very much better that the author should not pasteurise his results too freely. We congratulate Dr. Faught—and ourselves—on the fact that he has not done so.

COMPENDIUM OF THE PHARMACOPŒIAS. (*b*)

This useful collection of formularies and lists of drugs has now reached a fourth edition, and forms a handy manual of reference for the medical practitioner, pharmacist and senior student. Amongst the recent and unofficial preparations we note various omissions, which is perhaps inevitable. We should like, however, to see included many other useful preparations, such as Nativelle's digitaline, standardised drugs such as apocynum cannabinum, and the various glidine compounds with iodine, bromine and iron, which are doubteless excluded from lack of space. The well-known Basham's mixture, of such utility in chronic parenchymatous nephritis, is mentioned with its synonym on page 85, but its formula might well be given in full in the synopsis of the United States Pharmacopœia. The list of Latin terms used in prescription writing might be revised with advantage; "gargarissima," for example, would look better with one "s." The list of contents, as compared with the size of the book, is great, and we would venture to suggest that the practical help which this book undoubtedly affords would be still further increased if those portions of it which overlap and are almost identical with portions of other kindred works, were omitted. Such procedure would allow greater revision and expansion of the remainder.

(*a*) "Blood-pressure from the Clinical Standpoint." By Francis Ashley Faught, M.D., formerly Director of the Laboratory of Clinical Medicine of the Medico-Chirurgical Hospital, Philadelphia. Illustrated. Philadelphia: W. B. Saunders Company. 1913.

(*b*) Compendium of the Pharmacopœias and Formularies, with practical aids to prescribing and dispensing." By C. J. S. Thompson, Fellow of the Royal Society of Medicine, &c. Fourth edition. Pp. 360, including index. London: John Bale, Sons and Danielsson, Ltd.

Summary of Recent Medical Literature English and Foreign.

Specially compiled for The Medical Press and Circular.

Gastric Ulcer and Gastric Cancer.—Smithies (*Journ. Amer. Med. Assoc.*, November 15th, 1913) discusses the relation between chronic gastric ulcer and gastric cancer by the aid of an analysis of 566 cases which were operatively and pathologically demonstrated as gastric cancer at the Mayo Clinic. The sex ratio in gastric cancer was found to be approximately that of chronic gastric ulcer—3.1 males to 1 female. More than three-fourths of the cases of gastric cancer occur in persons between the ages of 40 and 70 years; more than one-half of those of chronic gastric ulcer (134 cases) between the ages of 40 and 70 years. A family history, or one of blood relationship, of gastric cancer existed in 9.2 per cent., and of tuberculosis in 1.2 per cent. of the cases. With regard to previous history, 41.8 per cent. of the patients who were proved to have gastric cancer had previously presented the symptoms of chronic ulcer; 17.8 per cent. presented the symptoms of "irregular" gastric ulcer, and 32.1 per cent. had the symptom-complex of gastric cancer without previous history of gastric trouble. Thus more than 60 per cent. of the patients who had gastric cancer presented a history of dyspepsia, and this history was generally that of chronic gastric ulcer. The length of time of all symptoms of the "primary" cancerous group (182 cases) was 7.1 months. The average length of time of the precancerous dyspeptic period in 239 cases was 11.4 years. In this group the supervening period of evident malignancy averaged 6.1 months. In 81 per cent. of the patients in whom prolonged dyspepsia had preceded cancer periodicity of the symptoms was noted in that stage, while in 99 per cent of the patients this periodicity disappeared when the process evidently became malignant. Vomiting was observed in more than 57 per cent. of the cases of gastric cancer, more than 40 per cent. exhibiting delayed vomiting. Of the entire group 15 per cent. gave a history of coffee-ground vomit. Delayed gastric emptying power was evident in nearly two-thirds of the cases in the primary cancer class and in nearly three-fourths of the non-primary division. In 55.4 per cent. of primary gastric cancer cases free hydrochloric acid was absent, and in the non-primary class it was absent in 49 per cent. of the cases. More than 98 per cent. of the gastric cancers were adenocarcinomata, and sarcoma occurred but once in the 566 cases. Benign and malignant ulcers have been found associated in the same stomach. K.

Enteric Fever and Water Disinfection.—Ellis and Perkins (*Cleveland Med. Journ.*, September, 1913) describe the results of their study of typhoid fever in Cleveland during the year 1912, during which year hypochlorite disinfection of the water supply was practically continuous. Typhoid fever in Cleveland showed a diminution of nearly one-half in the reported incidence, and one-half in the reported deaths, during the period considered. Comparison by months showed that this change was accounted for by the absence of a winter epidemic, and a marked diminution in the autumn epidemic, as well as a lowering of the totals all along the line. There was a marked increase of the population during the period, and the only sanitary change of extensive influence was the disinfection of the water supply, begun in September, 1911, though an active fly campaign in the early part of the summer must not be forgotten. The chlorine dosage of the water was diminished in February, and after this there was a steady rise in the typhoid incidence, though the small number of cases in the city made the total possible pollution of the water supply smaller than in previous years. A rise has continued ever since (chlorine dosage being always below the recommended figure), and at the time this article was submitted for publication conditions were not very dissimiliar to what they were before the beginning of the treatment of the water. It seemed, therefore, reasonable to conclude that the diminution noted immediately after the inauguration of the disinfectant treatment, and persistent to a degree roughly comparable to the adequacy of the chlorine dosage, was closely related to that treatment, and that the relation of the main periods of infection of the water, as noted in the City Laboratory, to the increases in the typhoid incidence are further evidence of a constant and variable water infection of a dangerous type. The original contention that unless an amount equivalent to 0.7 parts per million of actually available chlorine was used in the treatment of the water the results would be unsatisfactory, appears to be borne out by the investigation, and is further confirmed in a general manner by the findings in other cities where an amount equal to or greater than this has been found essential for successful disinfection. A weak dosage is of use only for those periods in which the water actually coming in contact with the disinfectant is weak in bacteria and organic matter, and the results of laboratory tests show that the variations in the quality of the water may be almost hourly in character. K.

Conduct of Pregnancy and Labour in Acute and Chronic Affections of the Heart.—Webster (*Surg., Gyn. and Obs.*, xvii., 3) says that the most serious cases are those in which the myocardium is degenerated, tending to cause cardiac dilatation, or in which, after former valvular disease, compensation has not been thoroughly established. If a patient with old cardiac disease becomes pregnant she should be put on strict *régime*, and should be protected from all physical and mental strain, special attention being given to the care of the skin, kidneys, and alimentary canal. If abortion or premature labour threatens, the uterus is better emptied. If signs of cardiac failure develop without signs of premature emptying of the uterus, it is best to keep the patient in bed and treat to improve the heart, waiting for a period of improvement to advise artificial termination of the pregnancy. When labour pains begin, the first stage should be conducted as in normal cases, but all straining should be avoided, and when the second stage is entered upon it is advisable to empty the uterus with forceps so as to avoid any strain from expulsive efforts, and at the same time to give vasodilator drugs. The contraction of the uterus puts further strain on the heart, and it is advisable that the placenta be gradually detached by the fingers introduced into the uterus, and if the right side of the heart is embarrassed some free bleeding should be allowed to occur, and this is easily obtained from the placental site in preference to bleeding from a vein. F.

The Conduct of Gynæcological and Obstetrical Operations with Endocarditis.—Polak (*Surg., Gyn. and Obs.*, xvii., 3) says that if compensation has ever been broken the tax of the last few weeks of pregnancy is usually so great that the margin of reserve is used up, and therefore no case should be allowed to go to full term. In the woman with chronic discompensation with myocardial change and renal insufficiency, the uterus should be emptied promptly, but this should be preceded by a pre-operative treatment to re-establish the cardiac balance. The earlier the uterus is emptied the less the cardiac strain. During labour the physical suffering should be partly relieved by morphia and the delivery left to nature as long as the heart is competent, but if signs of cardiac strain develop some form of artificial aid is indicated, and the operation may be done under ether-oxygen anæsthesia.

Immediately on the birth of the child there is a predisposition to congestion of the right heart, and this is increased by the closing of the placental sinuses. Bleeding from the placental site does not relieve this engorgement, but further weakens the patient, and so bleeding from the arm is recommended. When pregnancy has to be interrupted in multiparæ with a viable fœtus, induction should be done with the bag or bougies and the delivery left to nature, with forceps to hasten the second stage; while in primiparæ vaginal hysterotomy offers the greatest advantages.

F.

The Management of Puerperal Thrombophlebitis.—Findley (*Surg., Gyn. and Obs.*, xvii., 3), from his personal experience, concludes that Trendelenburg's operation is surgically correct, but as a practical proposition is a questionable procedure. The difficulties involved in making an accurate diagnosis are as yet insurmountable. It is not possible to judge the extent of the infection within the veins or elsewhere, even when the abdomen is opened; the sense of touch is unable to locate the limits of a thrombus, nor can the presence or absence of pus within the veins be judged with certainty. Failure to find bacteria in the blood gives no certainty of the localised character of the infection, nor can the condition of the lungs or other viscera be established. It is in direct violence to ordinary rules of practice to traumatise tissues in the immediate neighbourhood of a virulent infection. If the infected veins are not cut out the infection is only shut up by ligature above the zone of the infection, while the cutting out of the veins may disseminate the infection, and there is the risk of dislodging a thrombus in exploring the pelvic veins. It is a physical impossibility to ligate all the veins leading from the genital organs, and unless all channels are blocked there can be no assurance of stopping the infection. The physical resistance of all cases of puerperal infection is low, and the operation may only add to the burden. Little dependence can be placed on vaccines and serums. [The writer's views are in opposition to modern work in this country.]

F.

A New Method of Dealing with Scars.—Tubby (*Brit. Med. Journ.*, November 1st, 1913) advises the following original method. With a fine and strong-backed tenotomy knife a large number of multiple incisions are made transversely to the bands of keloid material. The incisions are made close together, not more than one-tenth of an inch apart; great care is taken that they should penetrate not only into the subcutaneous fat, but also extend one quarter of a half-inch into the neighbouring healthy skin. No attempt is made to arrest hæmorrhage except by pressure, and when bleeding has ceased a solution of thiosinamin is vigorously rubbed in, and if the scar tissue is very thick a few drops are injected into the most prominent bands. The writer does not hesitate to inject 15 min. at a time in a child and 20 min. in an adult. After the operation the part is put on a splint in as much extension as is possible without tearing the soft parts. This is accompanied by no excessive reaction and very little pain. After ten or fourteen days the wound will be healed and the mobility of the part increased by 50 per cent. The operation is then repeated and it rarely may be required three or four times. The results in over a dozen cases have been most satisfactory; scars which have been tough, resistant, and, in cases of the fingers, wire-like, have become soft and supple, the parts regaining their mobility, and their usefulness has been restored.

S.

A Method of Operation for Radical Cure of Inguinal Hernia.—Davies (*Brit. Med. Journ.*, September 20th, 1913) splits the external oblique as in Bassini's operation. The lower margin of the internal oblique is retracted upwards; the cord lying in its place is not disturbed. The peritoneum (not the sac) is opened from the internal ring upwards. When the abdominal cavity is opened the sac can be seen from the inside, and if omentum or other strictures are adherent they can be easily separated and drawn out of the sac. The lower end of the incision through the peritoneum is carried down to the neck of the sac and round it, so that the sac is separated like the finger of a glove cut off at the palm. The abdominal peritoneum is closed as in any other abdominal operation. By inserting a finger into the sac it can easily be dissected or swabbed out of its bed with little disturbance to the surrounding tissues. The operation is finished as in Bassini's method.

S.

MEDICAL NEWS & PASS LISTS.

Coroner and Medical Evidence—an Omagh Inquest.

There was an extraordinary development in the proceedings at a Coroner's inquest held on the 23rd inst. by Mr. Andrew C. Leitch, solicitor, in the Court House, Omagh, into the death by burning of a seven-year-old girl named Rose Hackett, of Omagh.

Evidence having been given by the mother and a neighbour, the Coroner expressed the opinion that, having regard to this evidence, the jury should have no difficulty in arriving at a verdict. Several jurors expressed disagreement with the Coroner, holding that medical evidence was essential, and one juror said the doctor who dressed the child's wounds should be heard.

The Coroner said this was a plain case, the facts were clear, and he was not going to run the risk of a surcharge of the doctor's fee when there was no necessity to call a doctor. It was not a matter for the jury what witnesses should be called.

A juror said that personally he was not satisfied that the evidence given was sufficient to enable the jury to arrive at a verdict. Another juror said, with all respect to the Coroner, medical evidence was produced in all such inquests..

Some heated remarks between the Coroner and the jury followed, and eventually the Coroner administered an oath to Sergeant Sadlier to take the jury in charge and keep them without food or light, and not allow them to speak or converse with any other person until they had arrived at a verdict. The jury were then locked up, the Coroner withdrawing to his office, while two constables kept guard at the door of the jury-room.

About an hour later the Coroner reappeared in response to a communication from the jury that they could not ascertain the cause of death in the absence of medical evidence.

The Coroner informed the jury that their verdict should be "Died as a result of burns." He recapitulated the evidence given by the witnesses, and again told the jury it was not their province to select witnesses, because if they were allowed to do so it would reduce Coroners' inquests to farces. If allowed to call witnesses the jury would be usurping his position. He then retired, subsequently reappearing with Dr. H. B. Fleming. Addressing the jury, the Coroner intimated that, although he did not consider it necessary, he had procured a medical witness.

Dr. Fleming then described the burns received by the child, and stated that burning was the cause of death. At the conclusion of his evidence, Dr. Todd, Medical Officer, walked into the room, and there ensued a sharp passage of words between him and the Coroner, the jury supporting Dr. Todd, and requesting the Coroner to apologise for remarks which they considered unjustifiable.

The Coroner said that it was his duty to tell them whether medical evidence was required or not, and in this case he was convinced there was no necessity for it. Some further angry remarks passed, and the jury, after long deliberation, returned a verdict that death was due to shock, caused by extensive burns, accidentally received.

The Lister Memorial at King's College.

It is announced that Lord Rayleigh will unveil a tablet to the memory of Lord Lister at King's College, London, on Wednesday, January 14th, at 4.30.

The Aberdeen Medico-Chirurgical Society.

The annual dinner of the Aberdeen Medico-Chirurgical Society was held on December 19th in the Society's Building, King Street. There was a large attendance. Dr. J. R. Levack, Chairman, presided. Professor Ashley W. Mackintosh, Vice-Chairman, was the croupier. After dinner a toast list and an enjoyable programme of music was submitted. The following was the toast list:—"The King and Queen"; "The Imperial Forces," by Dr. H. Edgar Smith, replied to by Captain Robertson, R.A.M.C. (T.F.); "The Founders of the Society," by Mr. J. Scott Riddell, M.V.O.; "The University and Medical School," by Mr. G. M. Cook, replied to by Emeritus Professor Stephenson and Dr. Thomas Fraser; "The Medico-Chirurgical Society," by Dr. Kenneth Gillies, replied to by Professor A. W. Mackintosh; "The Guests," by Dr. James Crombie, replied to by Dr. Robert Keith; and "The President," by Dr. David Lawson.

The Association of Registered Medical Women.

At a recent meeting of the Association of Registered Medical Women the following resolution was carried: "That the Association, while recognising that the proposed scheme for a women's medical service in India in many respects offers improved conditions for the work of women under the Dufferin Fund, desires strongly to protest against the scale of remuneration offered, which is entirely inadequate for the work which the medical women are asked to undertake, and also the subjection of medical women to a lay committee, for the constitution of which no guarantee is offered, yet which has the power of punishment for acts of which the committee may disapprove. The Association feels that these defects will be fatal to the success of the scheme, since no first-rate medical women will consent to work under such conditions."

The National Medical Union.

The Provisional Federating Council of the National Medical Union have formulated the following policy—viz.:—

(1) To maintain the freedom of the medical profession in its professional and personal relations with the public.

(2) To support the public in maintaining a corresponding freedom and to safeguard the national health.

(3) To oppose the present arrangements for medical benefits under the National Insurance Acts, and to decline professional service under such arrangements.

(4) To preserve an independent attitude with regard to party politics.

Since its inception at the Conference of the Non-Panel Associations held on November 29th, the National Medical Union has actively pushed forward the initial steps of organisation. New non-panel associations have been formed, and members in isolated positions in all parts of the country have been enrolled at headquarters.

In order that there shall be no misconception as to the objects of the National Medical Union, and in view of the crisis through which the medical profession is passing, it is necessary to make it clear that the Union is an organisation pledged solely to non-panel interests.

The Union is established in its offices in the "Morning Post" Buildings, 346 Strand, London, to which address all non-panel practitioners who are in sympathy with the above policy, and who have not already become members through their local non-panel association, should communicate.

Gift for Cancer Research.

Mr. Arnold Friedlander, merchant, of Messrs. J. and A. Friedlander, and of the Anglo-Transvaal Association, director of the United South Africa Association, Ltd., and other companies, a naturalised British subject, left estate in the United Kingdom of the gross value of £192,926, of which the net personalty has been sworn at £187,748.

The testator left £5,000 for a Cancer Research Fund, to be applied as his executors may direct towards increasing the knowledge of the cause, characteristics, and effects of cancer and allied diseases, and the best means of the prevention, alleviation and cure thereof.

Gift to a Hospital.

It is announced that the Brompton Hospital for Consumption and Diseases of the Chest has received from Mrs. C. Theodore Williams a cheque for £1,000 to name a ward in the Hospital in accordance with the wishes of the late Dr. C. Theodore Williams, who was attached to the Hospital as Physician and Consulting Physician for over 45 years.

University of Dublin.

A meeting of the Senate of Dublin University was held on Saturday, the 20th inst., for the purpose of conferring degrees. The following degrees in medicine were conferred:—

Baccalaurei in Medicina, in Chirurgia, et in Arte Obstetricia.—Ernestus Bantry-White, Fredricus G. Beatty, Guilelmus S. Boyd, Guilelmus St. L. Evans, Geoffrey M. M. Fleming, Guilelmus F. Gibson, Joseph Harvey, Reginald H. Jones, Jacobus C. Kelly, Percival G. Leeman, Johannes A. MacMahon, Stephanus J. Malherbe, Herbertus E. Murray, Guilelmus De Malet Peyton, Blacker C. Powell, Johannes G. C. Stubbs, Eleanor E. Taylor.

Baccalaureus in Medicina.—Jacobus C. M'Walter.

Doctores in Medicina.—Fredricus A. G. Davis, Jacobus H. Grove-White, Samuel G. S. Haughton, Jacobus C. Kelly, Dorothy K. Milne, Arturus F. B. Shaw.

In Absentia.—Doctor in Medicina.—Haroldus T. Marrable.

PASS LISTS.

The London School of Tropical Medicine.

The following candidates have passed the examinations during the October-December Session, 1913:—Passed with distinction: W. H. Kauntze (Colonial Service), M.B., B.S.Lond., M.R.C.S. A. R. Paterson, (Colonial Service), M.B., Ch.B.Glasg., M. F. Reaney (Capt. I.M.S.), M.B.Lond., D.P.H.Lond. Passed: D. T. Mitchell, M.R.C.V.S., R. F. Steel (Capt. I.M.S.), M.B.Dub., A. S. Burgess (Colonial Service), M.B., B.C., M.R.C.S., D. L. Graham (Capt. I.M.S.), M.B., Ch.B.Glasg., J. R. Ridlon (U.S. Public Health Service), M.D.Maine, R. Drummond (Colonial Service), M.R.C.S., L.R.C.P., T. P. Fraser (Colonial Service), M.B., B.Ch.Aber., D.P.H.Camb., E. H. Griffin, L.M.S.S.A., R. G. Perkins, M.D.Syracuse, C. R. Bakhle (Maj. I.M.S.), M.R.C.S., L.R.C.P., H. W. Furnival (Colonial Service), M.B., B.S.Durh., J. K. A. Hofmeyr, M.B., Ch.B.Edin., P. A. Clearkin (Colonial Service, M.B., B.Ch., B.A.OBelfast, E. J. H. Garstin (Colonial Service), M.D., L.M.L.S.Dub., A. I. Jackson, L.R.C.P. and S.Edin, K. Ghosh, L.M.S.Calcutta, L. R. Sharples (Colonial Service), M.B., B.Ch.Edin., Miss J. Crozier, M.D.Michigan, C. R. Avari (Assistant Surgeon, Indian Plague Commission), L. G. Fink, M.B., C.M.Edin., W. F. Masters, L.R.C.P.Lond., R. G. Ball (Colonial Service), M.B., B.Ch., B.A.O.Dub., Miss M. I. Balfour, M.B., C.M. Edin., M.D.Brux., J. R. Dodd (Colonel A.M.S.), M.D.Durh., F.R.C.S.Eng., D.P.H.Lond., G. V. Fiddian (Colonial Service), M.B., B.C.Camb., C. S. Harwood, M.B.Lond., D.P.H.Lond., S. Shepheard, M.R.C.S., L.R.C.P., B. Sefton, M.D.Brazil, D. S. Bryan-Brown, M.R.C.S., L.R.C.P., L. M. Bisvas, L.M.S.Calculla, C. B. Mack, M.D.Penn., J. Atkinson (Colonial Service), M.B., B.Ch.Glasg., E. B. Pearson, M.D.Illinois.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

BRITISH MEDICAL ASSOCIATION.

Just before going to press we are able to report that the Extraordinary General Meeting of the British Medical Association of the 30th December, has been held, and the new regulations carried by 12 to 1, some thirteen members being present. It is now, therefore, merely a matter of clerical procedure to raise the subscription to £2, and to extend the borrowing powers of the Association.

Mr. E. Fitch (London, E.).—We understand that the London Post-Graduate Association, 20 Hanover Square, London, W., is to be wound up to-day, December 31st.

WORKMEN'S COMPENSATION ACT, 1906.

The Secretary of State for the Home Department gives notice that he has decided to appoint a Specialist Medical Referee under the Workmen's Compensation Act, 1906, to act in all aural cases arising in the Sheriffdom of Lanarkshire in which the services of a Medical Referee are required. Applications for the post should be addressed to the Private Secretary, Scottish Office, and should reach him not later than 20th January, 1914.

M.B., B.S. (Brighton).—It is said that a solution of cellulose in acetone, known as "pelliculine," has been adopted by Dr. Guillaume-Louis, a surgeon of Tours, to prepare bandages in order to permit of their being used to hold injured limbs in position. It forms an incombustible and resistant film which is superior to celluloid, besides being much cheaper.

An Ipswich Reader.—The matter is dealt with editorially in our present issue. We agree that a more thorough inspection of imported food products should be carried out, though in the case of the metropolis the hands of the sanitary staff are already over full.

CHRISTMAS HOLIDAYS AND THE POST.

Several subscribers having notified us of the non-delivery of the weekly copy of this journal last week, it is probable that others have not received copies owing to the formidable difficulties of the postal service at Christmas. Should any of our readers who have not yet written us have failed to receive the number for December 24th, our publisher will be pleased to send a duplicate on receipt of post-card.

Dr. R. W. (Hants.).—The observations of Edmunds show that animals will survive total thyroparathyroidectomy if they are fed on large quantities of milk, but not if the milk be obtained from animals already thyroidectomised.

Mr. B. Wood (London, S.W.).—Our correspondent might apply to the Medical Superintendent, Northumberland House, Finsbury Park, N., where such cases are received.

Meetings of the Societies, Lectures, &c.

Monday, January 5th.

Rontgen Society.—The meeting will be held (by kind permission of the authorities), at the Middlesex Hospital, at 8.15 p.m. Paper (illustrated by lantern slides) by Dr. Jean Clunet, Paris, on "Histological Changes produced by X-rays on Animal Tissues; Destructive and Hyperplastic Action of X-rays; Practical consequences in regard to Radio-Therapy and protection of the Radiolgist."

Thursday, January 8th.

North-East London Clinical Society (Prince of Wales's Hospital, Tottenham).—4.15 p.m.: Address by Dr. Charles R. Box. Subject: "Pelagra" (with lantern demonstration). Election of members.

Appointments.

Burrow, J. le Fleming C., M.B., Ch.B.Edin., M.R.C.P.Lond., Honorary Physician to the Leeds Public Dispensary.

Deakin, H. V., M.R.C.S., L.R.C.P.Lond., House Surgeon at University College Hospital.

Gould, A. L. Pearce, M.B., B.Ch.Oxon., Obstetric Assistant to University College Hospital.

Lee, Harry, M.B., B.C.Cantab., F.R.C.S.Eng., Ophthalmic Surgeon to the Leeds Public Dispensary.

Marshall, Cole, M.D.Lond., F.R.C.S.Eng., Assistant Surgeon to the Western Ophthalmic Hospital

McLorinan, W., L.R.C.P. and S.Irel., Certifying Surgeon under the Factory and Workshop Acts for the Belfast, North, District of the County of Antrim.

Richards, Maude M., M.B., B.S.Lond., Clinical Assistant to the Throat Department at the Royal Free Hospital.

Salisbury, Walter, M.B., B.S.Lond., M.R.C.S., L.R.C.P.Lond., Resident Medical Officer at the Hospital for Women, Soho Square, W.

Trotter, Wilfred, M.S.Lond., F.R.C.S.Eng., Full Surgeon on the Staff of University College Hospital.

Walker, R. A., M.B., B.C.Cantab., F.R.C.S.Eng., Certifying Surgeon under the Factory and Workshop Acts for the Peterborough District of the County of Northampton.

Vacancies.

Warwick County Asylum, Hatton, near Warwick.—Second Assistant Medical Officer. Salary £200 per annum, with full board, lodging, and laundry. Applications to Dr. Miller, Medical Superintendent.

Nottingham General Dispensary.—Resident Surgeon. Salary £220 per annum, with apartments, attendance, light, and fuel. Applications to 12, Low Pavement, Nottingham.

County Asylum, Chester. Third Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Joint Counties Asylum, Carmarthen, South Wales.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Royal Mineral Water Hospital, Bath.—Resident Medical Officer. Salary £120, with lodging, board and washing. Applications to the Secretary.

Brentford Union.—First Assistant Medical Superintendent. Salary £185 per annum, with furnished apartments, rations, washing, etc. Applications to W. Stephens, Clerk to the Guardians, Union Offices, Isleworth, W.

London County Asylum, Claybury, Woodford Bridge, Essex.—Junior Assistant Medical Officer. Salary £200 a year, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk to the Asylums, Committee, Asylums Committee Office, 6, Waterloo Place, S.W.

Wilts County Asylum, Devizes.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, attendance and laundry. Applications to Guy W. Jackson, Clerk to the Committee.

Births.

Deane-Butcher.—On December 24th, at Pittsworth, Queensland, to Dr. C. B. and Mrs. Deane-Butcher, a son.

Dunkerton.—On December 27th, at 29 Kenilworth Court, Putney, S.W., the wife of Captain N. E. Dunkerton, R.A.M.C., of a son.

Marriages.

Lobb—Greenall.—On December 23rd, at Christ Church, Woburn Square, London, W.C., E. Leslie Martyn Lobb, M.S.Lond., F.R.C.S.Eng., of Hong Kong, China, only son of the Rev. J. and Mrs. Martyn Lobb, of Cheshunt, Herts., to Louise Josephine, eldest daughter of J. N. and Mrs. Greenall, of Nottingham.

Mutch—Lane.—On December 23rd, at St. George's Church, Hanover Square, W., Nathan Mutch, M.A., M.B., B.C. Cantab., M.R.C.P.Lond., eldest son of Mr. and Mrs. Nathan Mutch, of Rochdale, to Eileen, youngest daughter of Sir Arbuthnot and Lady Lane, of 21, Cavendish Square, W.

Powell—Griffiths.—On December 23rd, at Libanus Chapel, Blaenclydach, James Powell, M.R.C.S., L.R.C.P., second son of Mr. J. H. Powell, of Aberdare, to Bessie, daughter of Mr. R. S. Griffiths, J.P.

Robinson—Aldersmith.—On November 21st, at St. Paul's Cathedral, Calcutta, Chas. E. Robinson, of Assam, son of George Robinson, of Gainsborough, England, to Dorothy Constance, daughter of H. Aldersmith, F.R.C.S., M.B., Horsham, Sussex.

Deaths.

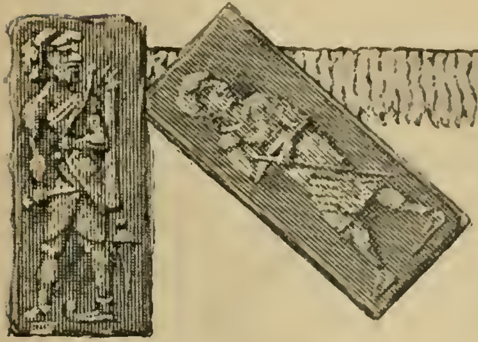
Brown.—On December 12th, at 2 Edgehill Road, Sheffield, John Henry Brown, M.D.Edin., M.R.C.S., aged 54.

Fleming.—On December 22nd, suddenly, Alexander John Fleming, M.D., of 3 Arkwright Road, N.W., son of the late Rev. Robert Winning Fleming, of Coleraine, Ireland.

Lipscombe.—On December 22nd, at 52 Cambridge Road, Hove, as the result of an accident, Richard Nicholson Lipscombe, M.R.C.S.Eng., L.S.A., aged 84.

Thornton.—On December 28th, at Berkeley Lodge, Trinity Square, Margate, Bertram Thornton, M.R.C.S., L.R.C.P., in his 57th year.

TEXTURÆ ANTIQUÆ, 2—AKKADIAN



How the Prescriber can Standardise the Dispensing of his Prescriptions—

By prescribing the fine products of Burroughs Wellcome & Co. whenever possible.

For example—'TABLOID' Brand products.

In number they are B.P. and more.

In reliability they are B.P. or BETTER.

They fulfil the spirit of the prescription.

They make for great certainty of obtaining satisfactory results.

They standardise dispensing all over the world.

COPIES OF UNSOLICITED TESTIMONIALS.

Dear Sirs,—"I find that most certainly the chest sounds are rendered clearer and more distinct by your 'Phonophore' than by any stethoscope I have used during over 30 years' work."—Yours, F.R.C.S.

Dear Sirs,—"I have found your 'Phonophore' by far the best stethoscope I have ever used."—Faithfully Yours.

Extract from the "British Medical Journal," Oct. 28th, 1911,—"Some years ago Messrs. Arnold & Sons, of Giltspur-street, E.C., brought out a stethoscope which they named the 'Phonophore.' Its construction secured a considerably increased volume of sound, and the appliance gained favour among those dissatisfied on general grounds with ordinary stethoscopes, or whose needs, owing to some lack of aural acuity, were not adequately met thereby. Of this appliance the same firm has recently brought out a modification in which the bell-like attachment constituting the chest-piece is provided with two sound tubes instead of one. These tubes are continued upwards, the sound thus being conveyed to each ear direct from the collecting chamber. Each ear, therefore, receives the same amount of sound, although the same amount of sound may not be perceived if there is any difference in the hearing power of the two ears. The gross volume of sound is also greater than supplied even by the original 'Phonophore.' This modification of the 'Phonophore' is worth examination by anyone interested in stethoscopy."
